BOBBIN ELECTROMAGNETIC FIELD PROPULSION VEHICLE

BRIEF SUMMARY OF THE INVENTION

[0001] This invention, which is the subject of my present application, is comprised of a toroidal core around which are wound a plurality of electromagnetic bobbins. The bobbins are pulsed electrically to create an amplified magnetic wave that travels around the core. At the same time, a circular electrical conductor carrying direct current creates a magnetic field around its area which results in the formation of a magnetic moment. This magnetic moment, together with the spacetime curvature distortion created by the traveling magnetic wave, produces a lift force on the vehicle.

REFERENCE PAPERS

[0002] Levitron, Hones, U.S. Pat. No. 5,404,062.

[0003] *Geometry of Electromagnetic Systems,* Paul Hammond, page 179.

BACKGROUND OF THE INVENTION

[0004] The idea for this invention comes from experiments I have done using thin transformer laminations wound in intervals with bobbins of wire connected to a frequency generator. Pulsing the bobbins electrically creates a slow traveling magnetic wave along the surface of the lamination. The velocity of the wave, as shown by Hammond in the reference paper, is the square root of the frequency divided by the conductivity and permeability of the material. From Einstein's General Theory of Relativity, this type of wave around the circumference creates a spacetime curvature distortion in the vertical direction that looks like a tilted plate. The magnetic field traveling around the circumference has to follow this curvature. This creates a magnetic gradient in the z-direction which together with the magnetic moment developed by a solenoid produces lift on the vehicle.

SUMMARY OF THE INVENTION

[0005] It is the object of this invention to create a magnetic field gradient and magnetic moment in order to produce a lift force on the hull of a vehicle. The magnetic field gradient is produced by a traveling magnetic wave which produces a tilting-plate spacetime curvature around the hull. The magnetic moment is created by a simple circular wire carrying direct current around its area.

[0013] **FIG. 7**. The spacetime curvature G_{zz} in the vertical direction created by the magnetic wave traveling around the core.

[0014] **FIG. 8**. Tilted plate spacetime curvature showing magnetic gradient.

DETAILED DESCRIPTION OF THE INVENTION

[0015] 1. Referring to the equation in **FIG. 1**, the lift force on the bobbin spacecraft is equal to its magnetic moment times its magnetic field gradient. The magnetic moment has units of electrical current, measured in amps, times the area enclosed by the current. Thus the units of the magnetic moment are amp–m^2. The magnetic moment can be created by a large, circular coil of wire carrying direct current I as shown in **FIG. 2**. The spacetime cylindrical coordinates $\{t, r, \theta, z\}$ are shown to the right of the drawing where t is time, r the radius, the horizontal angle θ, and the vertical height z.

[0016] 2. The wire coil solenoid also produces a magnetic field in the vertical z-direction equal to the permeability of space μ times the number of turns per unit length of the solenoid n, times the current I in the winding. The equation is shown in **FIG. 3** which can be developed from Ampere's law that the magnetic field around a loop is equal to the current passing through the loop.

[0017] 3. Referring to **FIG. 4**, the bobbin spacecraft consists of a large, horizontal, highpermeability toroidal core (D) wrapped at intervals with electrical bobbins (B) which can be pulsed electrically to create a traveling magnetic wave around the core. Interior to this core is a large direct current solenoid (C) which produces said magnetic field in the z-direction. These devices are enclosed in a circular hull (A) containing the coils on the outer rim and a cabin area in the center.

[0018] 4. Referring to **FIG. 5**, the velocity of the magnetic wave on the surface of the core is equal to the square root of the wave frequency ω divided by the conductivity a times the permeability μ of the core material. When the first bobbin is pulsed, a wave starts to propagate along the surface of the core. As the wave passes the second bobbin in sequence, another electrical pulse is generated to amplify the wave. After many cycles, the wave traveling around the core becomes larger and larger in amplitude.

[0019] 5. A traveling wave has a wave function equal to a sinusoidal function with an argument of the angle θ around the periphery less the time t, or $\text{Sin}[\theta-\omega t]$.

[0020] 6. In gravitational physics, there is a g metric tensor which is a measure of length in spacetime coordinates. When mass or electromagnetic fields are involved in a certain region of space, a curvature of space is created. The curvature of space can then be calculated directly from this metric tensor. The result is Einstein's G curvature tensor which shows the spacetime distortion. The g metric tensor is a 4 by 4 matrix having rows and columns equal to time t, radius r, angle theta, and vertical height z. The diagonal from top left to bottom right has a signature equal to $\{-1, 1, r^2, 1\}$.

[0021] 7. Because the magnetic wave traveling around the core is varying with time t in the theta direction, the wave function has to go into the $\{t,\theta\}$ and $\{\theta,t\}$ slots of the metric tensor, as shown in **FIG. 6**.

[0022] 8. From this metric tensor, Einstein's G curvature tensor is calculated using a general relativity software program. The spacetime curvature in the vertical z-direction is contained in the G_{zz} component. A 3D plot of this curvature with respect to radius and theta is shown in **FIG. 7**. The axis on the right side is the angle around the periphery, and the axis on the left is the radius which goes from 0 to 20 meters. The vertical axis of the graph is the spacetime curvature in the vertical z-direction. The center of the vertical axis is zero. At a small radius, there is a sinusoidal curvature which is positive from 0 to π and which is negative from π to 2π. What this looks like is a tilted plate as depicted in **FIG. 8**.

[0023] 9. In flat spacetime with no electromagnetic fields or mass, the curvature would be the horizontal plate as seen **FIG. 8**. Due to the traveling magnetic wave, the spacetime curvature looks like the tilted plate. The flat-space magnetic field was pointing up in the vertical direction, having no divergence and no gradient. In curved spacetime, however, the magnetic field becomes tilted just like the plate and a magnetic gradient dB_z/dz is created. This spacetime curvature gradient of the magnetic field times the magnetic moment of the second coil produces a lift force on the hull which is anchored to these coils.

What I claim as my invention is:

1. A spacecraft that generates a magnetic moment and a magnetic field gradient in the vertical direction in order to create a lift force on the hull.

2. A toroidal core wrapped with electrical bobbins at intervals around the core whose purpose is to create and amplify a magnetic wave that travels along the surface of the core.

3. A circular, direct-current carrying solenoid, located radially inside the toroidal core, to create the magnetic moment.

4. Said magnetic surface wave creates a spacetime curvature, similar to a tilted plate, which produces a magnetic field gradient in the vertical direction.

5. A circular hull, with interior cabin, electrical power supply to drive the coils, and a computer to calculate and sequence the activation of the electrical bobbins.

6. Magnetic sensors, in the form of small coils, located on the toroidal core which can detect the velocity and position of the traveling magnetic wave as feedback to the computer control system.

7. A magnetic vortex generator, either rotating magnet or dual coil, to produce a wormhole through which low linear mass and low speed of light hyperspace energy can enter the hull in order to create highly relativistic electromagnetic fields.

8. A variable current generator to modulate the direct current in the coil so as to produce a variable magnetic moment that can control lift, hover and descent.

9. An electrical power supply using mechanical flywheel stored energy together with a large area capacitor, resupplied with energy by solar cells located on the outer surface of the hull.

(57) ABSTRACT

An electromagnetic generator without moving parts includes a permanent magnet and a magnetic core including first and second magnetic paths. A first input coil and a first output coil extend around portions of the first magnetic path, while a second input coil and a second output coil extend around portions of the second magnetic path. The input coils are alternatively pulsed to provide induced current pulses in the output coils. Driving electrical current through each of the input coils reduces a level of flux from the permanent magnet within the magnet path around which the input coil extends. In an alternative embodiment of an electromagnetic generator, the magnetic core includes annular spaced-apart plates, with posts and permanent magnets extending in an alternating fashion between the plates. An output coil extends around each of these posts. Input coils extending around portions of the plates are pulsed to cause the induction of current within the output coils.

POWER GENERATION WITHIN A MOTIONLESS ELECTROMAGNETIC GENERATOR

[0001] This application is a continuation of a copending U.S. application Ser. No. 09/656,313, filed 09/06/00, titled "Motionless Electromagnetic Generator," for which the issue fee has been paid.

BACKGROUND INFORMATION

[0002] 1. Field of Invention

[0003] This invention relates to a magnetic generator used to produce electrical power without moving parts, and, more particularly, to such a device having a capability, when operating, of producing electrical power without an external application of input power through input coils.

[0004] 2. Description of the Related Art

[0005] The patent literature describes a number of magnetic generators, each of which includes a permanent magnet, two magnetic paths external to the permanent magnet, each of which extends between the opposite poles of the permanent magnet, switching means for causing magnetic flux to flow alternately along each of the two magnetic paths, and one or more output coils in which current is induced to flow by means of changes in the magnetic field within the device. These devices operate in accordance with an extension of Faraday's Law, indicating that an electrical current is induced within a conductor within a changing magnetic field, even if the source of the magnetic field is stationary.

[0006] A method for switching magnetic flux to flow predominantly along either of two magnetic paths between opposite poles of a permanent magnet is described as a "flux transfer" principle by R. J. Radus in *Engineer's Digest,* Jul. 23, 1963. This principle is used to exert a powerful magnetic force at one end of both the north and south poles and a very low force at the other end, without being used in the construction of a magnetic generator. This effect can be caused mechanically, by keeper movement, or electrically, by driving electrical current through one or more control windings extending around elongated versions of the pole pieces **14**. Several devices using this effect are described in U.S. Pat. Nos. 3,165,723, 3,228,013, and 3,316,514, which are incorporated herein by reference.

[0007] Another step toward the development of a magnetic generator is described in U.S. Pat. No. 3,368,141, which is incorporated herein by reference, as a device including a permanent magnet in combination with a transformer having first and second windings about a core, with two paths for magnetic flux leading from each pole of the permanent magnet to either end of the core, so that, when an alternating current induces magnetic flux direction changes in the core, the magnetic flux from the permanent magnet is automatically directed through the path which corresponds with the direction taken by the magnetic flux through the core due to the current. In this way, the magnetic flux is intensified. This device can be used to improve the power factor of a typically inductively loaded alternating current circuit.

[0008] Other patents describe magnetic generators in which electrical current from one or more output coils is described as being made available to drive a load, in the more conventional manner of a generator. For example, U.S. Pat. No. 4,006,401, which is incorporated herein by reference, describes an electromagnetic generator including permanent magnet and a core member, in which the magnetic flux flowing from the magnet in the core member is rapidly alternated by switching to generate an alternating current in a winding on the core member. The device includes a permanent magnet and two separate magnetic flux circuit paths between the north and south poles of the magnet. Each of the circuit paths includes two switching means for alternately opening and closing the circuit paths, generating an alternating current in a winding on the core member. Each of the switching means includes a switching magnetic circuit intersecting the circuit path, with the switching magnetic circuit having a coil through which current is driven to induce magnetic flux to saturate the circuit path extending to the permanent magnet. Power to drive these coils is derived directly from the output of a continuously applied alternating current source. What is needed is an electromagnetic generator not requiring the application of such a current source.

[0009] U.S. Pat. No. 4,077,001, which is incorporated herein by reference, describes a magnetic generator, or dc/dc converter, comprising a permanent magnet having spaced-apart poles and a permanent magnetic field extending between the poles of the magnet. A variable-reluctance core is disposed in the field in fixed relation to the magnet and the reluctance of the core is varied to cause the pattern of lines of force of the magnetic field to shift. An output conductor is disposed in the field in fixed relation to the magnet and is positioned to be cut by the shifting lines of permanent magnetic force so that a voltage is induced in the conductor. The magnetic flux is switched between alternate paths by means of switching coils extending around portions of the core, with the flow of current being alternated between these switching coils by means of a pair of transistors driven by the outputs of a flip-flop. The input to the flip flop is driven by an adjustable frequency oscillator. Power for this drive circuit is supplied through an additional, separate power source. What is needed is a magnetic generator not requiring the application of such a power source.

[0010] U.S. Pat. No. 4,904,926, which is incorporated herein by reference, describes another magnetic generator using the motion of a magnetic field. The device includes an electrical winding defining a magnetically conductive zone having bases at each end, the winding including elements for the removing of an induced current therefrom. The generator further includes two pole magnets, each having a first and a second pole, each first pole in magnetic communication with one base of the magnetically conductive zone. The generator further includes a third pole magnet, the third pole magnet oriented intermediately of the first poles of the two pole electromagnets, the third pole magnet having a magnetic axis substantially transverse to an axis of the magnetically conductive zone, the third magnet having a pole nearest to the conductive zone and in magnetic attractive relationship to the first poles of the two pole electromagnets, in which the first poles thereof are like poles. Also included in the generator are elements, in the form of windings, for cyclically reversing the magnetic polarities of the electromagnets. These reversing means, through a cyclical change in the magnetic polarities of the electromagnets, cause the magnetic flux lines associated with the magnetic attractive relationship between the first poles of the electromagnets and the nearest pole of the third magnet to correspondingly reverse, causing a wiping effect across the magnetically conductive zone, as lines of magnetic flux swing between respective first poles of the two electromagnets, thereby inducing electron movement within the output windings and thus generating a flow of current within the output windings.

[0011] U.S. Pat. No. 5,221,892, which is incorporated herein by reference, describes a magnetic generator in the form of a direct current flux compression transformer including a magnetic envelope having poles defining a magnetic axis and characterized by a pattern of magnetic flux lines in polar symmetry about the axis. The magnetic flux lines are spatially displaced relative to the magnetic envelope using control elements which are mechanically stationary relative to the core. Further provided are inductive elements which are also mechanically stationary relative to the magnetic envelope. Spatial displacement of the flux relative to the inductive elements causes a flow of electrical current. Further provided are magnetic flux valves which provide for the varying of the magnetic reluctance to create a time domain pattern of respectively enhanced and decreased magnetic reluctance across the magnetic valves, and, thereby, across the inductive elements.

[0012] Other patents describe devices using superconductive elements to cause movement of the magnetic flux. These devices operate in accordance with the Meissner effect, which describes the expulsion of magnetic flux from the interior of a superconducting structure as the structure undergoes the transition to a superconducting phase. For example, U.S. Pat. No. 5,011,821, which is incorporated herein by reference, describes an electric power generating device including a bundle of conductors which are placed in a magnetic field generated by north and south pole pieces of a permanent magnet. The magnetic field is shifted back and forth through the bundle of conductors by a pair of thin films of superconductive material. One of the thin films is placed in the superconducting state while the other thin film is in a non-superconducting state. As the states are cyclically reversed between the two films, the magnetic field is deflected back and forth through the bundle of conductors.

[0013] U.S. Pat. No. 5,327,015, which is incorporated herein by reference, describes an apparatus for producing an electrical impulse comprising a tube made of superconducting material, a source of magnetic flux mounted about one end of the tube, a means, such as a coil, for intercepting the flux mounted along the tube, and a means for changing the temperature of the superconductor mounted about the tube. As the tube is progressively made superconducting, the magnetic field is trapped within the tube, creating an electrical impulse in the means for intercepting. A reversal of the superconducting state produces a second pulse.

[0014] None of the patented devices described above use a portion of the electrical power generated within the device to power the reversing means used to change the path of magnetic flux. Thus, like conventional rotary generators, these devices require a steady input of power, which may be in the form of electrical power driving the reversing means of one of these magnetic generators or the torque driving the rotor of a conventional rotary generator. Yet, the essential function of the magnetic portion of an electrical generator is simply to switch magnetic fields in accordance with precise timing. In most conventional applications of magnetic generators, the voltage is switched across coils, creating magnetic fields in the coils which are used to override the fields of permanent magnets, so that a substantial amount of power must be furnished to the generator to power the switching means, reducing the efficiency of the generator.

[0015] Recent advances in magnetic material, which have particularly been described by Robert C. O'Handley in *Modern Magnetic Materials, Principles and Applications,* John Wiley & Sons, New York, pp. 456-468, provide nanocrystalline magnetic alloys, which are particularly well suited for the rapid switching of magnetic flux. These alloys are primarily composed of crystalline grains, or crystallites, each of which has at least one dimension of a few nanometers. Nanocrystalline materials may be made by heat-treating amorphous alloys which form precursors for the nanocrystalline materials, to which insoluble elements, such as copper, are added to promote massive nucleation, and to which stable, refractory alloying materials, such as niobium or tantalum carbide are added to inhibit grain growth. Most of the volume of nanocrystalline alloys is composed of randomly distributed crystallites having dimensions of about 2-40 nm. These crystallites are nucleated and grown from an amorphous phase, with insoluble elements being rejected during the process of crystallite growth. In magnetic terms, each crystallite is a single-domain particle. The remaining volume of nanocrystalline alloys is made up of an amorphous phase in the form of grain boundaries having a thickness of about 1 nm.

[0016] Magnetic materials having particularly useful properties are formed from an amorphous Co—Nb—B (cobalt-niobium-boron) alloy having near-zero magnetostriction and relatively strong magnetization, as well as good mechanical strength and corrosion resistance. A process of annealing this material can be varied to change the size of crystallites formed in the material, with a resulting strong effect on DC coercivity. The precipitation of nanocrystallites also enhances AC performance of the otherwise amorphous alloys.

[0017] Other magnetic materials are formed using iron-rich amorphous and nanocrystalline alloys, which generally show larger magnetization that the alloys based on cobalt. Such materials are, for example, Fe—B—Si—Nb—Cu (iron-boron-silicon-niobium-copper) alloys. While the permeability of iron-rich amorphous alloys is limited by their relatively large levels of magnetostriction, the formation of a nanocrystalline material from such an amorphous alloy dramatically reduces this level of magnetostriction, favoring easy magnetization.

[0018] Advances have also been made in the development of materials for permanent magnets, particularly in the development of materials including rare earth elements. Such materials include samarium cobalt, $SmCo_5$, which is used to form a permanent magnet material having the highest resistance to demagnetization of any known material. Other magnetic materials are made, for example, using combinations of iron, neodymium, and boron.

SUMMARY OF THE INVENTION

[0019] It is a first objective of the present invention to provide a magnetic generator which a need for an external power source during operation of the generator is eliminated.

[**0020**] It is a second objective of the present invention to provide a magnetic generator in which a magnetic flux path is changed without a need to overpower a magnetic field to change its direction.

[**0021**] It is a third objective of the present invention to provide a magnetic generator in which the generation of electricity is accomplished without moving parts.

[**0022**] In the apparatus of the present invention, the path of the magnetic flux from a permanent magnet is switched in a manner not requiring the overpowering of the magnetic fields. Furthermore, a process of self-initiated iterative switching is used to switch the magnetic flux from the permanent magnet between alternate magnetic paths within the apparatus, with the power to operate the iterative switching being provided through a control circuit consisting of components known to use low levels of power. With self-switching, a need for an external power source during operation of the generator is eliminated, with a separate power source, such as a battery, being used only for a very short time during start-up of the generator.

[**0023**] According to a first aspect of the present invention, an electromagnetic generator is provided, including a permanent magnet, a magnetic core, first and second input coils, first and second output coils, and a switching circuit. The permanent magnet has magnetic poles at opposite ends. The magnetic core includes a first magnetic path, around which the first input and output coils extend, and a second magnetic path, around which the second input and output coils extend, between opposite ends of the permanent magnet. The switching circuit drives electrical current alternately through the first and second input coils. The electrical current driven through the first input oil causes the first input coil to produce a magnetic field opposing a concentration of magnetic flux from the permanent magnet within the first magnetic path. The electrical current driven through the second input coil causes the second input coil to produce a magnetic field opposing a concentration of magnetic flux from the permanent magnet within the second magnetic path.

[**0024**] According to another aspect of the present invention, an electromagnetic generator is provided, including a magnetic core, a plurality of permanent magnets, first and second pluralities of input coils, a plurality of output coils, and a switching circuit. The magnetic core includes a pair of spaced-apart plates, each of which has a central aperture, and first and second pluralities of posts extending between the spaced-apart plates. The permanent magnets each extend between the pair of spaced apart plates. Each permanent magnet has magnetic poles at opposite ends, with the magnetic fields of all the permanent magnets being aligned to extend in a common direction. Each input coil extends around a portion of a plate within the spaced-apart plates, between a post and a permanent magnet. An output coil extends around each post. The switching circuit drives electrical current alternately through the first and second pluralities of input coils. Electrical current driven through each input coil in the first plurality of input coils causes an increase in magnetic flux within each post within the first plurality of posts from permanent magnets on each side of the post and a decrease in magnetic flux within each post within the second plurality of posts from permanent magnets on each side of the post. Electrical current driven through each input coil in the second plurality of input coils causes a decrease in magnetic flux within each post within the first plurality of posts from permanent magnets on each side of the post and an increase in magnetic flux within each post within the second plurality of posts from permanent magnets on each side of the post.

[**0043**] **FIG. 12** is a top view of a magnetic generator built in accordance with a second version of the second embodiment of the present invention.

DETAILED DESCRIPTION OF THE INVENTION

[0044] **FIG. 1** is a partly schematic front elevation of an electromagnetic generator **10**, built in accordance with a first embodiment of the present invention to include a permanent magnet **12** to supply input lines of magnetic flux moving from the north pole **14** of the magnet **12** outward into magnetic flux path core material **16**. The flux path core material **16** is configured to form a right magnetic path **18** and a left magnetic path **20**, both of which extend externally between the north pole **14** and the south pole **22** of the magnet **12**. The electromagnetic generator **10** is driven by means of a switching and control circuit **24**, which alternately drives electrical current through a right input coil **26** and a left input coil **28**. These input coils **26**, **28** each extend around a portion of the core material **16**, with the right input coil **26** surrounding a portion of the right magnetic path **18** and with the left input coil **28** surrounding a portion of the left magnetic path **20**. A right output coil **29** also surrounds a portion of the right magnetic path **18**, while a left output coil **30** surrounds a portion of the left magnetic path **20**.

[0045] In accordance with a preferred version of the present invention, the switching and control circuit **24** and the input coils **26**, **28** are arranged so that, when the right input coil **26** is energized, a north magnetic pole is present at its left end **31**, the end closest to the north pole **14** of the permanent magnet **12**, and so that, when the left input coil **28** is energized, a north magnetic pole is present at its right end **32**, which is also the end closest to the north pole **14** of the permanent magnet **12**. Thus, when the right input coil **26** is magnetized, magnetic flux from the permanent magnet **12** is repelled from extending through the right input coil **26**. Similarly, when the left input coil **28** is magnetized, magnetic flux from the permanent magnet **12** is repelled from extending through the left input coil **28**.

[0046] Thus, it is seen that driving electrical current through the right input coil **26** opposes a concentration of flux from the permanent magnet **12** within the right magnetic path **18**, causing at least some of this flux to be transferred to the left magnetic path **20**. On the other hand, driving electrical current through the left input coil **28** opposes a concentration of flux from the permanent magnet **12** within the left magnetic path **20**, causing at least some of this flux to be transferred to the right magnetic path **18**.

[0047] While in the example of **FIG. 1**, the input coils **26**, **28** are placed on either side of the north pole of the permanent magnet **12**, being arranged along a portion of the core **16** extending from the north pole of the permanent magnet **12**, it is understood that the input coils **26**, **28** could as easily be alternately placed on either side of the south pole of the permanent magnet **12**, being arranged along a portion of the core **16** extending from the south pole of the permanent magnet **12**, with the input coils **26**, **28** being wired to form, when energized, magnetic fields having south poles directed toward the south pole of the permanent magnet **12**. In general, the input coils **26**, **28** are arranged along the magnetic core on either side of an end of the permanent magnet forming a first pole, such as a north pole, with the input coils being arranged to produce magnetic fields of the polarity of the first pole directed toward the first pole of the permanent magnet.

[0048] Further in accordance with a preferred version of the present invention, the input coils **26**, **28** are never driven with so much current that the core material **16** becomes saturated. Driving the core material **16** to saturation means that subsequent increases in input current can occur without effecting corresponding changes in magnetic flux, and therefore that input power can be wasted. In this way, the apparatus of the present invention is provided with an advantage in terms of the efficient use of input power over the apparatus of U.S. Pat. No. 4,000,401, in which a portion both ends of each magnetic path is driven to saturation to block flux flow. In the electromagnetic generator **10**, the switching of current flow within the input coils **26**, **28** does not need to be sufficient to stop the flow of flux in one of the magnetic paths **18**, **20** while promoting the flow of magnetic flux in the other magnetic path. The electromagnetic generator **10** works by changing the flux pattern; it does not need to be completely switched from one side to another.

[0049] Experiments have determined that this configuration is superior, in terms of the efficiency of using power within the input coils **26**, **28** to generate electrical power within the output coils **29**, **30**, to the alternative of arranging input coils and the circuits driving them so that flux from the permanent magnet is driven through the input coils as they are energized. This arrangement of the present invention provides a significant advantage over the prior-art methods shown, for example, in U.S. Pat. No. 4,077,001, in which the magnetic flux is driven through the energized coils.

[0050] The configuration of the present invention also has an advantage over the prior-art configurations of U.S. Pat. Nos. 3,368,141 and 4,077,001 in that the magnetic flux is switched between two alternate magnetic paths **18**, **20** with only a single input coil **26**, **28** surrounding each of the alternate magnetic paths. The configurations of U.S. Pat. Nos. 3,368,141 and 4,077,001 each require two input coils on each of the magnetic paths. This advantage of the present invention is significant both in the simplification of hardware and in increasing the efficiency of power conversion.

[0051] The right output coil **29** is electrically connected to a rectifier and filter **33**, having an output driven through a regulator **34**, which provides an output voltage adjustable through the use of a potentiometer **35**. The output of the linear regulator **34** is in turn provided as an input to a sensing and switching circuit **36**. Under start up conditions, the sensing and switching circuit **36** connects the switching and control circuit **24** to an external power source **38**, which is, for example, a starting battery. After the electromagnetic generator **10** is properly started, the sensing and switching circuit **36** senses that the voltage available from regulator **34** has reached a predetermined level, so that the power input to the switching and control circuit **24** is switched from the external power source **38** to the output of regulator **34**. After this switching occurs, the electromagnetic generator **10** continues to operate without an application of external power.

[0052] The left output coil **30** is electrically connected to a rectifier and filter **40**, the output of which is connected to a regulator **42**, the output voltage of which is adjusted by means of a potentiometer **43**. The output of the regulator **42** is in turn connected to an external load **44**.

[0053] **FIG. 2** is a schematic view of a first version of the switching and control circuit **24**. An oscillator **50** drives the clock input of a flip-flop **54**, with the Q and Q' outputs of the flip-flop **54** being connected through driver circuits **56**, **58** to power FETS **60**, **62** so that the input coils **26**, **28** are alternately driven. In accordance with a preferred version of the present invention, the voltage V applied to the coils **26**, **28** through the FETS **60**, **62** is derived from the output of the sensing and switching circuit **36**.

[**0054**] **FIG. 3** is a graphical view of the signals driving the gates of FETS **60**, **62** of **FIG. 2**, with the voltage of the signal driving the gate of FET **60** being represented by line **64**, and with the voltage of the signal driving FET **62** being represented by line **66**. Both of the coils **26**, **28** are driven with positive voltages.

[**0055**] **FIG. 4** is a schematic view of a second version of the switching and control circuit **24**. In this version, an oscillator **70** drives the clock input of a flip-flop **72**, with the Q and Q' outputs of the flip-flop **72** being connected to serve as triggers for one-shots **74**, **76**. The outputs of the one-shots **74**, **76** are in turn connected through driver circuits **78**, **80** to drive FETS **82**, **84**, so that the input coils **26**, **28** are alternately driven with pulses shorter in duration than the Q and Q' outputs of the flip flop **72**.

[**0056**] **FIG. 5** is a graphical view of the signals driving the gates of FETS **82**, **84** of **FIG. 4**, with the voltage of the signal driving the gate of FET **82** being represented by line **86**, and with the voltage of the signal driving the gate of FET **84** being represented by line **88**.

[**0057**] Referring again to **FIG. 1**, power is generated in the right output coil **29** only when the level of magnetic flux is changing in the right magnetic path **18**, and in the left output coil **30** only when the level of magnetic flux is changing in the left magnetic path **20**. It is therefore desirable to determine, for a specific magnetic generator configuration, the width of a pulse providing the most rapid practical change in magnetic flux, and then to provide this pulse width either by varying the frequency of the oscillator **50** of the apparatus of **FIG. 2**, so that this pulse width is provided with the signals shown in **FIG. 3**, or by varying the time constant of the one-shots **74**, **76** of **FIG. 4**, so that this pulse width is provided by the signals of **FIG. 5** at a lower oscillator frequency. In this way, the input coils are not left on longer than necessary. When either of the input coils is left on for a period of time longer than that necessary to produce the change in flux direction, power is being wasted through heating within the input coil without additional generation of power in the corresponding output coil.

[**0058**] A number of experiments have been conducted to determine the adequacy of an electromagnetic generator built as the generator **10** in **FIG. 1** to produce power both to drive the switching and control logic, providing power to the input coils **26**, **28**, and to drive an external load **44**. In the configuration used in this experiment, the input coils **26**, **28** had 40 turns of 18-gauge copper wire, and the output coils **29**, **30** had 450 turns of 18-gauge copper wire. The permanent magnet **12** had a height of 40 mm (1.575 in. between its north and south poles, in the direction of arrow **89**, a width of 25.4 mm (1.00 in.), in the direction of arrow **90**, and in the other direction, a depth of 38.1 mm (1.50 in.). The core **16** had a height, in the direction of arrow **89**, of 90 mm (3.542 in.), a width, in the direction of arrow **90**, of 135 mm (5.315 in.) and a depth of 70 mm (2.756 in.). The core **16** had a central hole with a height, in the direction of arrow **89**, of 40 mm (1.575 mm) to accommodate the magnet **12**, and a width, in the direction of arrow **90**, of 85 mm (3.346 in.). The core **16** was fabricated of two "C"-shaped halves, joined at lines **92**, to accommodate the winding of output coils **29**, **30** and input coils **26**, **28** over the core material.

[**0059**] The core material was a laminated iron-based magnetic alloy sold by Honeywell as METGLAS Magnetic Alloy 2605SA1. The magnet material was a combination of iron, neodymium, and boron.

[**0060**] The input coils **26**, **28** were driven at an oscillator frequency of 87.5 KHz, which was determined to produce optimum efficiency using a switching control circuit configured as shown in **FIG. 2**. This frequency has a period of 11.45 microseconds. The flip flop **54** is arranged, for example, to be set and reset on rising edges of the clock signal input from the oscillator, so that each pulse driving one of the FETS **60**, **62** has a duration of 11.45 microseconds, and so that sequential pulses are also separated to each FET are also separated by 11.45 microseconds.

[**0061**] FIGS. 6A-6H are graphical views of signals which simultaneously occurred within the apparatus of **FIGS. 1 and 2** during operation with an applied input voltage of 75 volts. **FIG. 6A** shows a first drive signal **100** driving FET **60**, which conducts to drive the right input coil **26**. **FIG. 6B** is shows a second drive signal **102** driving FET **62**, which conducts to drive the left input coil **28**.

[**0062**] **FIGS. 6C and 6D** show voltage and current signals associated with current driving both the FETS **60**, **62** from a battery source. **FIG. 6C** shows the level **104** of voltage V. While the nominal voltage of the battery was 75 volts, a decaying transient signal **106** is superimposed on this voltage each time one of the FETS **60**, **62** is switched on to conduct. The specific pattern of this transient signal depends on the internal resistance of the battery, as well as on a number of characteristics of the magnetic generator **10**. Similarly, **FIG. 6D** shows the current **106** flowing into both FETS **60**, **62** from the battery source. Since the signals **104**, **106** show the effects of current flowing into both FETS **60**, **62** the transient spikes are 11.45 microseconds apart.

[**0063**] FIGS. 6E-6H show voltage and current levels measured at the output coils **29**, **30**. **FIG. 6E** shows a voltage output signal **108** of the right output coil **29**, while **FIG. 6F** shows a voltage output signal **110** of the left output coil **30**. For example, the output current signal **116** of the right output coil **29** includes a first transient spike **112** caused when the a current pulse in the left input coil **28** is turned on to direct magnetic flux through the right magnetic path **18**, and a second transient spike **114** caused when the left input coil **28** is turned off with the right input coil **26** being turned on. **FIG. 6G** shows a current output signal **116** of the right output coil **29**, while **FIG. 6H** shows a current output signal **118** of the left output coil **30**.

[**0064**] **FIG. 7** is a graphical view of output power measured using the electromagnetic generator **10** and eight levels of input voltage, varying from 10 v to 75 v. The oscillator frequency was retained at 87.5 KHz. The measurement points are represented by indicia **120**, while the curve **122** is generated by polynomial regression analysis using a least squares fit.

[**0065**] **FIG. 8** is a graphical view of a coefficient of performance, defined as the ratio of the output power to the input power, for each of the measurement points shown in **FIG. 7**. At each measurement point, the output power was substantially higher than the input power. Real power measurements were computed at each data point using measured voltage and current levels, with the results being averaged over the period of the signal. These measurements agree with RMS power measured using a Textronic THS730 digital oscilloscope.

[**0066**] While the electromagnetic generator **10** was capable of operation at much higher voltages and currents without saturation, the input voltage was limited to 75 volts because of voltage limitations of the switching circuits being used. Those skilled in the relevant art will understand that components for switching circuits capable of handling higher voltages in this application are readily available. The experimentally-measured data was extrapolated to describe operation at an input voltage of 100 volts, with the input current being 140 ma, the input power being 14 watts, and with a resulting output power being 48 watts for each of the two output coils **29**, **30**, at an average output current of 12 ma and an average output voltage of 4000 volts. This means that for each of the output coils **29**, **30**, the coefficient of performance would be 3.44.

[**0067**] While an output voltage of 4000 volts may be needed for some applications, the output voltage can also be varied through a simple change in the configuration of the electromagnetic generator **10**. The output voltage is readily reduced by reducing the number of turns in the output windings. If this number of turns is decreased from 450 to 12, the output voltage is dropped to 106.7, with a resulting increase in output current to 0.5 amps for each output coil **29**, **30**. In this way, the output current and voltage of the electromagnetic generator can be varied by varying the number of turns of the output coils **29**, **30**, without making a substantial change in the output power, which is instead determined by the input current, which determines the amount of magnetic flux shuttled during the switching process.

[**0068**] The coefficients of performance, all of which were significantly greater than 1, plotted in **FIG. 8** indicate that the output power levels measured in each of the output coils **29**, **30** were substantially greater than the corresponding input power levels driving both of the input coils **26**, **28**. Therefore, it is apparent that the electromagnetic generator **10** can be built in a self-actuating form, as discussed above in reference to **FIG. 1**. In the example of **FIG. 1**, except for a brief application of power from the external power source **38**, to start the process of power generation, the power required to drive the input coils **26**, **28** is derived entirely from power developed within the right output coil **29**. If the power generated in a single output coil **29**, **30** is more than sufficient to drive the input coils **26**, **28**, an additional load **126** may be added to be driven with power generated in the output coil **29** used to generate power to drive the input coils **26**, **28**. On the other hand, each of the output coils **29**, **30** may be used to drive a portion of the input coil power requirements, for example with one of the output coils **26**, **28** providing the voltage V for the FET **60** (shown in **FIG. 2**), while the other output coil provides this voltage for the FET **62**.

[**0069**] Regarding thermodynamic considerations, it is noted that, when the electromagnetic generator **10** is operating, it is an open system not in thermodynamic equilibrium. The system receives static energy from the magnetic flux of the permanent magnet. Because the electromagnetic generator **10** is self-switched without an additional energy input, the thermodynamic operation of the system is an open dissipative system, receiving, collecting, and dissipating energy from its environment; in this case, from the magnetic flux stored within the permanent magnet. Continued operation of the electromagnetic generator **10** causes demagnetization of the permanent magnet. The use of a magnetic material including rare earth elements, such as a samarium cobalt material or a material including iron, neodymium, and boron is preferable within the present invention, since such a magnetic material has a relatively long life in this application.

[**0070**] Thus, an electromagnetic generator operating in accordance with the present invention should be considered not as a perpetual motion machine, but rather as a system in which flux radiated from a permanent magnet is converted into electricity, which is used both to power the apparatus and to power an external load. This is analogous to a system including a nuclear reactor, in which a number of fuel rods radiate energy which is used to keep the chain reaction going and to heat water for the generation of electricity to drive external loads.

[**0071**] **FIG. 9** is a cross-sectional elevation of an electromagnetic generator **130** built in accordance with a second version of the first embodiment of the present invention. This electromagnetic generator **130** is generally similar in construction and operation to the electromagnetic generator **10** built in accordance with the first version of this embodiment, except that the magnetic core **132** of the electromagnetic generator **10** is built in two halves joined along lines **134**, allowing each of the output coils **135** to be wound on a plastic bobbin **136** before the bobbin **136** is placed over the legs **137** of the core **132**. **FIG. 9** also shows an alternate placement of an input coil **138**. In the example of **FIG. 1**, both input coils **26**, **28** were placed on the upper portion of the magnetic core **16**, with these coils **26**, **28** being configured to establish magnetic fields having north magnetic poles at the inner ends **31**, **32** of the coils **26**, **28**, with these north magnetic poles thus being closest to the end **14** of the permanent magnet **12** having its north magnetic pole. In the example of **FIG. 9, a** first input coil **26** is as described above in reference to **FIG. 1**, but the second input coil **138** is placed adjacent the south pole **140** of the permanent magnet **12**. This input coil **138** is configured to establish a south magnetic pole at its inner end **142**, so that, when input coil **138** is turned on, flux from the permanent magnet **12** is directed away from the left magnetic path **20** into the right magnetic path **18**.

[**0072**] **FIGS. 10 and 11** show an electromagnetic generator **150** built in accordance with a first version of a second embodiment of the present invention, with **FIG. 10** being a top view thereof, and with **FIG. 11** being a front elevation thereof. This electromagnetic generator **150** includes an output coil **152**, **153** at each corner, and a permanent magnet **154** extending along each side between output coils. The magnetic core **156** includes an upper plate **158**, a lower plate **160**, and a square post **162** extending within each output coil **152**, **153**. Both the upper plate **158** and the lower plate **160** include central apertures **164**.

[**0073**] Each of the permanent magnets **154** is oriented with a like pole, such as a north pole, against the upper plate

158. Eight input coils **166**, **168** are placed in positions around the upper plate **158** between an output coil **152**, **153** and a permanent magnet **154**. Each input coil **166**, **168** is arranged to form a magnetic pole at its end nearest to the adjacent permanent magnet **154** of a like polarity to the magnetic poles of the magnets **154** adjacent the upper plate **158**. Thus, the input coils **166** are switched on to divert magnetic flux of the permanent magnets **154** from the adjacent output coils **152**, with this flux being diverted into magnetic paths through the output coils **153**. Then, the input coils **168** are switched on to divert magnetic flux of the permanent magnets **154** from the adjacent output coils **153**, with this flux being diverted into magnetic paths through the output coils **152**. Thus, the input coils form a first group of input coils **166** and a second group of input coils **168**, with these first and second groups of input coils being alternately energized in the manner described above in reference to **FIG. 1** for the single input coils **26**, **28**. The output coils produce current in a first train of pulses occurring simultaneously within coils **152** and in a second train of pulses occurring simultaneously within coils **153**.

[**0074**] Thus, driving current through input coils **166** causes an increase in flux from the permanent magnets **154** within the posts **162** extending through output coils **153** and a decrease in flux from the permanent magnets **154** within the posts **162** extending through output coils **152**. On the other hand, driving current through input coils **168** causes a decrease in flux from the permanent magnets **154** within the posts **162** extending through output coils **153** and an increase in flux from the permanent magnets **154** within the posts **162** extending through output coils **152**.

[**0075**] While the example of **FIGS. 10 and 11** shows all of the input coils **166**, **168** deployed along the upper plate **158**, it is understood that certain of these input coils **166**, **168** could alternately be deployed around the lower plate **160**, in the manner generally shown in **FIG. 9**, with one input coil **166**, **168** being within each magnetic circuit between a permanent magnet **154** and an adjacent post **162** extending within an output coil **152**, **153**, and with each input coil **166**, **168** being arranged to produce a magnetic field having a magnetic pole like the closest pole of the adjacent permanent magnet **154**.

[**0076**] **FIG. 12** is a top view of a second version **170** of the second embodiment of the present invention, which is similar to the first version thereof, which has been discussed in reference to **FIGS. 10 and 11**, except that an upper plate **172** and a similar lower plate (not shown) are annular in shape, while the permanent magnets **174** and posts **176** extending through the output coils **178** are cylindrical. The input coils **180** are oriented and switched as described above in reference to **FIGS. 9 and 10**.

[**0077**] While the example of **FIG. 12** shows four permanent magnets, four output coils and eight input coils it is understood that the principles described above can be applied to electromagnetic generators having different numbers of elements. For example, such a device can be built to have two permanent magnets, two output coils, and four input coils, or to have six permanent magnets, six output coils, and twelve input coils.

[**0078**] In accordance with the present invention, material used for magnetic cores is preferably a nanocrystalline alloy, and alternately an amorphous alloy. The material is preferably in a laminated form. For example, the core material is a cobalt-niobium-boron alloy or an iron based magnetic alloy.

[**0079**] Also in accordance with the present invention, the permanent magnet material preferably includes a rare earth element. For example, the permanent magnet material is a samarium cobalt material or a combination of iron, neodymium, and boron.

[**0080**] While the invention has been described in its preferred versions and embodiments with some degree of particularity, it is understood that this description has been given only by way of example and that numerous changes in the details of construction, fabrication, and use, including the combination and arrangement of parts, may be made without departing from the spirit and scope of the invention.

What is claimed is:

1. A method for generating electrical power, wherein

said method comprises driving electrical current alternately through a first input coil extending around a first portion of a first magnetic path and a second input coil extending around a first portion of a second magnetic path, inducing a flow of electrical current through a first output coil extending around a second portion of said first magnetic path due to changes in magnetic flux within said first magnetic path, and inducing a flow of electrical current through a second output coil extending around a second portion of said first magnetic path due to changes in magnetic flux within said second magnetic path,

said first magnetic path includes a first U-shaped magnetic structure extending in a first direction between opposite poles at opposite ends of a permanent magnet,

said second magnetic path includes a second U-shaped magnetic structure extending in a second direction between said opposite poles at said opposite ends of said permanent magnet,

electrical current driven through said first input coil produces a magnetic field opposing a concentration of magnetic flux from said permanent magnet within said first magnetic path, and

electrical current driven through said second input coil produces a magnetic field opposing a concentration of magnetic flux from said permanent magnet within said second magnetic path.

2. The method of claim 1, wherein

said permanent magnet has a pole of a first type at a first end,

said first input coil is displaced along said first magnetic path adjacent said first end of said permanent magnet,

said second input coil is displaced along said second magnetic path adjacent said first end of said permanent magnet,

driving said electrical current through said first input coil causes a magnetic field to be generated having a pole of said first type at an end of said first input coil adjacent said permanent magnet, and

driving said electrical current through said second input coil causes a magnetic field to be generated having a pole of said first type at an end of said second input coil adjacent said permanent magnet.

3. The method of claim 1, wherein

said permanent magnet has a pole of a first type at a first end and of a second type at a second end, opposite said first end,

said first input coil is displaced along said first magnetic path adjacent said first end of said permanent magnet,

said second input coil is displaced along said second magnetic path adjacent said second end of said permanent magnet,

driving said electrical current through said first input coil causes a magnetic field to be generated having a pole of said first type at an end of said first input coil adjacent said permanent magnet, and

driving said electrical current through said second input coil causes a magnetic field to be generated having a pole of said second type at an end of said second input coil adjacent said permanent magnet.

4. The method of claim 1, additionally comprising:

driving a switching and control circuit by an external power source during a starting process, wherein said switching and control circuit drives said electrical current alternately through said first and second input coils

rectifying a first portion of said flow of electrical current through said first and second output coils to form a first rectified output current; and

driving said switching and control circuit by said first portion of said flow of electrical current following said starting process.

5. The method of claim 4, additionally comprising rectifying a second portion of said flow of electrical current through said first and second output coils to form a second rectified output current flowing through an external load.

6. The method of claim 5, wherein said first portion of said flow of electrical current flows through said first output coil, and said second portion of said flow of electrical current flows through said second output coil.

7. The method of claim 1, wherein said first and second input coils are alternately driven for time periods of approximately 11.5 milliseconds.

8. The method of claim 1, wherein each said U-shaped magnetic structure is composed of a nanocrystalline magnetic alloy.

9. The method of claim 8, wherein said nanocrystalline magnetic alloy is a cobalt-niobium-boron alloy.

10. The method of claim 8, wherein said nanocrystalline magnetic alloy is an iron-based alloy.

11. The method of claim 1, wherein said changes in magnetic flux within said first and second magnetic paths occur without driving said first and second paths to magnetic saturation.

12. A method for generating electrical power, wherein

said method comprises driving electrical current alternately through a first and a second plurality of input coils, and inducing a flow of current within first and second pluralities of output coils by changes in magnetic flux within a magnetic core extending through said input coils and said output coils,

said magnetic core includes an upper plate section extending around an upper aperture, a lower plate section, spaced apart from said upper plate section, extending around a lower aperture, and a plurality of posts extending in a first pattern around said upper and lower apertures and between said upper and lower plates,

a plurality of permanent magnets extend in a second pattern around said upper and lower apertures and between said upper plate section and said lower plate section,

each post within said plurality of posts extends between an adjacent pair of permanent magnets within said plurality of permanent magnets,

each permanent magnet within said plurality of permanent magnets extends between an adjacent pair of posts within said plurality of posts,

all permanent magnets within said plurality of permanent magnets have a pole of a first type at an end adjacent said upper plate and a pole of a second type at an end adjacent said lower plate,

each input coil in said first plurality of input coils extends around a plate section within said magnetic core between a permanent magnet and a post extending through an output coil in said first plurality of output coils adjacent said permanent magnet and spaced apart from said permanent magnet in a first direction along said plate section, being oriented to oppose a concentration of flux extending from said permanent magnet through said input coil when electrical current is driven through said input coil, and

each input coil in said second plurality of input coils extends around a plate section within said magnetic core between a permanent magnet an a post extending through an output coil in said second plurality of output coils adjacent said permanent magnet and spaced apart from said permanent magnet opposite said first direction along said plate section, being oriented to oppose a concentration of flux extending from said permanent magnet through said input coil when electrical current is driven through said input coil.

13. The method of claim 12, wherein each input coil in said first and second pluralities of input coils extends around said upper plate section.

14. The method of claim 12, wherein

each input coil in said first plurality of input coils extends around said upper plate section, and

each input coil in said second plurality of input coils extends around said lower plate section.

(57) **ABSTRACT**

A method for employing sinusoidal oscillations of electrical bombardment on the surface of one Kerr type singularity in close proximity to a second Kerr type singularity in such a method to take advantage of the Lense-Thirring effect, to simulate the effect of two point masses on nearly radial orbits in a 2+1 dimensional anti-de Sitter space resulting in creation of circular timelike geodesics conforming to the van Stockum under the Van Den Broeck modification of the Alcubierre geometry (Van Den Broeck 1999) permitting topology change from one spacelike boundary to the other in accordance with Geroch's theorem (Geroch 1967) which results in a method for the formation of Godel-type geodesically complete spacetime envelopes complete with closed timelike curves.

METHOD OF GRAVITY DISTORTION AND TIME DISPLACEMENT

FIELD OF THE INVENTION

[0001] The present invention relates to the use of technical time displacement devices, which operate by the modification of gravitational fields. These drive systems do not depend on the emission of matter to create thrust to take advantage of time dilation, but rather create a change in the curvature of space-time, in accordance with general relativity. This allows travel across topologies by warping space-time, to produce a topology change from one spacelike boundary to the other in accordance with Geroch's theorem (Geroch 1967)

THEORETICAL BACKGROUND OF THE INVENTION

[0002] The concept of gravity should be examined in the light of quantum gravity and in turn as a component of quantum physics itself. The fundamental minimal quantum of energy in quantum physics is Planck's constant; h. Thus in accordance with the energy equivalence formula $E=mc^2$, the fundamental minimum quantity of mass (m_q) can therefore be derived, from known constants by; $m_q=h/c^2$ (1). Taking this minimal mass, it is possible to show that the formation of all matter, the forces of nature and indeed space-time itself derive from this single quintessential quantity.

[0003] Thus if the number of quintessences in a system is; $n_q=m/m_q$: then the total Energy of the system is more logically given by, the energy of a single quintessence (h); directly multiplied by the number of quintessences (n_q) in that system, thus

$$E=hn_q=mc^2 \qquad (1\text{ a}).$$

[0004] Furthermore, this minimal mass, termed quintessence, can form the basis of the existence of a quantum gravitational field in the form of a space-time lattice, from which quantum gravity may be derived from first principles. Furthermore, the conglomeration of these quintessences also accounts for the formation of the elementary particles and the forces acting between them, as in superstring theory. This concept explains the formation of matter and the forces of nature on a quantum mechanical basis and directly explains the existence of wave particle duality. Thus as $n_q=m/m_q$; the frequency of light and matter (f) is determined, directly, from the number of constituent quintessences. This leads automatically to the fundamental equation, derived from (1), $f=n_q=E/h$, where n_q is the number of quintessences, which leads directly to the frequency of both light and matter. This in turn leads directly to a Universal wave equation for matter and light $\lambda=c/\beta n_q=hc/\beta E$ (2), where β is the relative directional velocity, v/c. As the momentum, $p=\beta\times E/c$, then this equation also gives the standard de-Broglie wave equation, $\lambda=h/p$ in agreement with current theory and experiments[1].

[0005] Using the Universal wave equation, the standard equation for special relativity, $m'=m_o/(1-\beta^2)^{1/2}$, derives from first principles. Also from these observations, a modified Dirac wave equation may be derived, $E\psi=(-j\beta\cdot\nabla+\beta m)\psi$ (2a), the results of which have been recently verified by a paper in which the orbitals of electrons were experimentally directly visualised[2]. Moreover, a fundamental equation for general relativity can be formulated, where G is the gravitational constant and r_q is the given radius of quintessence; $G=9(r_q)^2c^4/\lambda\beta E$ (3), such that the Universal wave equation is in direct agreement with general relativity[3]. Thus special and general relativity and quantum mechanics can be unified.

[0006] From here it is possible to proceed in a number of ways; the geometric structure of the electron and the forces of Nature may be derived from first principles and in turn the structure of the quarks, including the top and bottom, otherwise known as truth and beauty can be seen. Moreover, the presence of a space-time lattice results in an understanding of quantum EPR effects. By allowing a theoretical flow of energy through the space-time lattice it can be shown that:

[0007] Energy is not bound by space-time

[0008] Thus logically accounting for phenomena such as entanglement and quantum tunnelling. Quintessence can also be used to explain, logically, the inner physics of a black hole, the missing mass of the Galaxy, the continuing expansion of the Universe, Guth's inflationary theory and the Big Bang. Hence, it is now possible to understand the Universe, including space-time, matter and the forces of nature from the radius, mass and vibration of a single quantity, quintessence.

[0009] With this understanding of space-time, matter and the forces of Nature, and in particular gravity, it is possible to demonstrate that the modification of gravitational fields, and in turn the warping of space-time, can be technically readily achieved.

[0010] Using standard equations for special relativity, $m'=m_0/(1-\beta^2)^{1/2}$, it can be demonstrated that by differentially increasing the velocity of electrons, by applying a differential current, their mass can be increased in a specific way. In turn by increasing the mass of electrons, by general relativity, the number of gravitons emitted from these electrons can be modulated. By multiplying this effect using an ultracentrifugational device the differential graviton emission can be manifestly amplified. This in turn, in accordance with general relativity, will cause a change in the curvature of space-time.

[0011] This effective warping of space-time does not, of necessity, imply superluminal velocities, but does allow the creation of warp drive systems, which do not depend on the creation of thrust by the ejection of material as used in current space technologies.

Part 1—Fundamental Laws of Physics

[0012] Quintessential Mass

[0013] The quantum physical, minimum component of energy is Planck's constant; h. To define the minimal component of mass, using the standard energy equivalence formula; $E=mc^2$, such a minimal mass (m_q) would be required to have the value equivalent to; $m_q=h/c^2$ (1). The total mass of a system (m) would then be; $m=n_qm_q$, where (n_q) is the number of these minimal units. Thence, the total energy of a system can be derived from the minimal energy; h, multiplied by the number of these energy units (n_q). Thus as, $E=mc^2$, then also $E=m_qn_qc^2$ and substituting $m_q=h/c^2$, the energy equivalence formula has the more logical formulation; $E=hn_q$(1a). Thus the energy of a system is equivalent to the minimal energy unit; h, multiplied by the number of those minimal energy units (n_q).

[0014] Taking this minimal mass/energy, it is possible to show that all matter, the forces of nature and space time can be constructed from this single quintessential quantity. Moreover, using this quantity the laws of physics can be derived from first principles. Thus, a priori, all components of the physical universe, including space-time, can be constructed from this minimal mass component, termed quintessence.

[0015] Wave Particle Duality

[0016] If the presence of quintessence accounts for the structure of matter and if matter itself forms from the number of quintessences, then the frequency of matter and thus wave particle duality directly arises from first principles. Specifically the wavelength of matter derives from the vibration of quintessence from which it is constituted. Thus the frequency (f) and in turn the wavelength of light and matter is directly equivalent to the number of quintessences contained within it. We find that the actual frequency of light can be directly derived from first principles from the effective mass of the photon (m,) and thus by the number of quintessences (n_q) it contains.

[0017] Thus for light conventionally:

$$f=E/h$$

[0018] and if $E=mc^2$, and $h=m_qc^2$, then

$$f=m_\gamma c^2/m_q c^2$$

and

$$f=m_\gamma/m_q=n_q$$

Thus

$$f=n_q \tag{4}$$

[0019] Thus the formula for the frequency of light E=hf is now readily explained by the observation that the frequency is determined quite directly from the number of quintessences n_q within the photon.

[0020] The wavelength is thus also given by:

$$\lambda=c/f=m_{qc}/m_\gamma=h/p$$

[0021] We can now show that the frequency of matter also has the same derivation from quintessence, as has the frequency of light. The frequency of matter is again equivalent to the number of quintessences it contains. Thus the wave particle duality of matter itself can be explained by its composition from quintessence. The amount of quintessences contained within a electron sphere will depend on the number of quintessences constituting the electron and those passing through it as a result of its relative velocity β^2 (where $\beta=v/c$); effectively its relativistic momentum (p). The frequency will then be related to the total number of quintessences. Thus for matter,

$$f=\beta^2 n_q \tag{4a}$$

[0022] Thus it is possible to derive the conventional de Broglie wave equation for matter from first principles. Thus, as $\lambda=v/f$, we have:

$$\lambda=v/\beta^2 n_q \tag{5}$$

[0023] thus as $n_q=E/h$

$$\lambda=hc/\beta E \tag{2}$$

[0024] and as conventionally $\beta E/c=p$, then for matter:

$$\lambda=h/p$$

[0025] Provided that in the de Broglie equation, the momentum of the object is calculated using the relativistic mass, thus accounting for the total number of quintessences n_q in an object, this gives an accurate value for the wavelength of matter[1].

[0026] Thus the wavelength of matter follows directly from its constituents, quintessence. As matter is made of quintessence, similarly to light, its frequency depends on the number of quintessences n_q within it, traveling relative to the speed of light. Moreover, $\lambda=hc/\beta E$, underpins a fundamental relationship between wavelength and energy. Furthermore, this is mathematically the same as the term $\lambda=hv/\beta^2 E$, giving a relativistic expression for the wavelength of matter, from which the relativistic equations may be directly derived

[0027] Wave Equations

[0028] The derivation of wave particle duality from first principles also now allows the derivation of a modified wave equation for matter.

[0029] To derive his wave equation Shrodinger commenced with the de Broglie equation using momentum (p). For lower energies the momentum of an electron is conventionally derived from the kinetic energy of the electron and the mass of the electron m_0. Thus conventionally:

$$E_k = \frac{1}{2}mv^{1/2} \quad \text{and} \quad p = m_0 v$$

Thus

$$E_k = p^2/2m_0$$

then

$$p = \sqrt{(E_k \cdot 2m_0)}$$

[0030] and conventionally, the de Broglie equation can also be written as:

$$\lambda=h/p=h/\sqrt{(E_k \cdot 2m_0)}$$

[0031] In turn the Shrodinger wave equation directly derives from the square of the above classical non relativistic term for kinetic energy:

$$\lambda^2 = h^2/E_k \cdot 2m_0$$

$$\text{thus } E_k = \frac{h^2}{2m} \cdot \frac{1}{\lambda^2}$$

$$\text{As } E = E_k + V$$

$$\text{then } E\psi = -\frac{h^2}{2m} \cdot \frac{d^2\psi}{dx^2} + V\psi = jh \cdot \frac{d\psi}{dt}$$

[0032] However, the Shrodinger equation, may be refined by taking into account relativity. Thus the true values for the energy are given by the relativistic momentum (p).

[0033] A fundamental relativistic wave equation for ψ, and its logical derivation may now be developed through the concept of quintessence as a fundamental constituent of matter.

[0034] The amount of quintessences in the electron is determined by the number of quintessences forming the electron at rest, plus the amount of quintessences passing through it due to its relativistic velocity, which will determine the relativistic momentum (p) of a particle.

[0035] The frequency of matter can now be readily calculated from first principles to give a more accurate result. Thus as matter is made of quintessence, similarly to light, its frequency is equal to the number of quintessences n_q within it. The wavelength will depend on its velocity travelling relative to the speed of light and thus multiplied by the relative velocity compared to c(β=v/c);

[0036] Hence for matter as previously shown:

$$\beta=v/\beta^2 n_q=hc/\beta E \tag{2}$$

[0037] And conventionally

$$E=(p^2c^2+m_0^2c^4)^{1/2}$$

[0038] Using these equations, we can now, also, reformulate the Shrodinger wave equation, which has the advantage that relativity can be treated in a quantum mechanical way. Thus if the wave energy of matter is defined as:

$$E_\lambda = \frac{\beta\sqrt{p^2c^2+m_0^2c^4}}{c^2}$$

thus

$$E_\lambda = \sqrt{(\beta^2p^2/c^2)+\beta^2m_0^2}$$

[0039] which in complex space generalises to

$$E_\psi=(-j\beta\cdot\nabla+\beta m)_\psi \tag{2a}$$

[0040] As the term

$$\alpha = \frac{e^2}{hc}4\pi\varepsilon_0;$$

also represents the ground state ratio of the velocity of the electron to c. Thus α=β=v/c=1/137.

[0041] Thus, also

$$E_\psi=(-j\alpha\cdot\nabla+\beta m)_\psi$$

[0042] This is thus the standard relativistic equation that Dirac was able to construct from the Shrodinger wave equation. This relativistic equation can be derived from the modified wave equation. This takes into account the relative mass energy which the quintessential wave equation contains.

[0043] Where importantly the term β·m is the mass m, multiplied by the ratio of the relative velocity to light β=v/c, and the term a is also essentially the relative velocity of the electron.

[0044] The Dirac equation was an empirical formula which worked mathematically, nevertheless even Dirac admitted it was not logically understood. The importance of these equations is that they show that the existence of quintessence allows the waveparticle duality of matter to be explained and mathematically derived from first principles, Thus the frequency of matter or even light is simply determined by the number of quintessences it contains.

[0045] Indeed, a recent publication in Nature has suggested that the direct visualisation of the orbitals of electrons shows that these are in very close agreement with theory. However, there is a significant departure from theory, in the interstitial molecular regions, suggesting that the higher velocities of the electrons obey the modified Dirac equation. Thus these orbitals were in keeping with the modified Dirac equation, which itself may be derived from the wave equation above, λ=hc/βE

[0046] The Shrodinger wave equation will approximate to the correct values until v approaches c. Indeed the Shrodinger equation will give similar answers as that derived from equation, under most experimental conditions.

[0047] However, equation 2 and its derivative may have advantages over standard Shrodinger theory with relativistic speeds. Furthermore, equation 2, conceptually shows that the wave particle duality of matter derives from the principle that the frequency of matter is directly equal to the number of quintessences it contains. Importantly it also mathematically allows relativity and quantum mechanics to be united.

[0048] With v≅c, the modified Dirac equation will yield more accurate results, particularly compared with the Schrodinger equation. We also find that the equation λ=hc/βE is equivalent to the de Broglie wave equation, λ=h/p, provided we use the relativistic mass in the de Broglie equation. Given this, these equations yield accurate experimental results.

[0049] Thus we find that the modified formulation of de Broglie wave equation λ=hc/βE leads directly to a modified Dirac relativistic wave equation and is supported by recent experiments which measure the wavelength of matter and demonstrate the electron orbitals experimentally from these wave equations for matter.

[0050] Wave Particle Duality and Relativity

[0051] From here it is possible to proceed in several ways using the relativistic wave equation. It is apparent that the reintroduction of the term for relative velocity into the wave equations will enable the reintroduction of special relativity into quantum mechanics. In particular we should now be able to derive the term

$$\sqrt{\left(1-\frac{v^2}{c^2}\right)}$$

as a special case of quantum mechanics.

[0052] Thus if:

$$\lambda = hc/\beta E$$

As $E=\sqrt{p^2c^2+m_0^2c^4}$, squaring

$$\lambda^2 = \frac{h^2c^2}{\beta^2\cdot(p^2c^2+m_0^2c^4)}$$

-continued

Conventionally $p^2c^2 = \frac{E^2v^2}{c^2}$

then

$$\lambda^2 = \frac{h^2c^2}{\beta^2 \cdot ((E^2v^2/c^2) + m_0^2c^4)}$$

Thus as $\beta^2 = \frac{v^2}{c^2}$ and $m_0^2c^4 = E_0^2$, then:

$$\beta^4E^2 + \beta^2E_0^2 = \frac{h^2c^2}{\lambda^2}$$

hence $\beta^4E^2 = h^2c^2 \cdot \frac{1}{\lambda^2} - \beta^2m_0^2c^4$ thus

$$\beta^2 = \frac{h^2c^2}{\beta^2E^2} \cdot \frac{1}{\lambda^2} - \frac{\beta^2m_0^2c^4}{\beta^2E^2}$$

As $E^2 = m^2c^4$

$$\beta^2 = \frac{h^2c^2}{\beta^2m^2c^4} \cdot \frac{1}{\lambda^2} - \frac{\beta^2m_0^2c^4}{\beta^2E^2}$$

Substituting $h = m_qc^2$

$$\beta^2 = \frac{m_q^2c^6}{\beta^2m^2c^4} \cdot \frac{1}{\lambda^2} - \frac{\beta^2m_0^2c^4}{\beta^2E^2}$$

As $m_q/'m = 1/n_q$ (eq. 2)

$$\beta^2 = \frac{c^2}{\beta^2n_q^2} \cdot \frac{1}{\lambda^2} - \frac{\beta^2m_0^2c^4}{\beta^2E^4}$$

Thus if $f = \beta^2n_q$; (eq. 7a)

$$\beta^2 = \frac{v^2}{f^2} \cdot \frac{1}{\lambda^2} - \frac{\beta^2m_0^2c^4f^2}{\beta^2E^2}$$

As $1/\lambda^2 = f^2/v^2$

$$\beta^2 = \frac{v^2}{f^2} \cdot \frac{f^2}{v^2} - \frac{\beta^2m_0^2c^4f^2}{\beta^2E^2}$$

Thus

$$\beta^2 = 1 - \frac{\beta^2m_0^2c^4}{\beta^2E^2}$$

As $E^2 = m^2c^4$

$$\beta^2 = 1 - \frac{m_0^2}{'m^2}$$

Hence

$$m_0/'m = (1 - \beta^2)^{1/2}$$

Thus

$$'m = m_0 \Big/ \left[1 - \frac{v^2}{c^2}\right]^{1/2}$$

[0053] Thus this derivation now allows relativity as a universal case of the quintessential wave nature of matter.

[0054] The original premises on which special relativity was based were: that the speed of light is a constant and that all observers are equal. As the speed of light has dimensions of length and time but not apparently of mass, the relativistic change in mass is not accounted for. Using quintessence logically and directly accounts for the relativistic mass changes.

[0055] Moreover, relativity can be derived from the de Broglie equation, and visa versa, directly, thus linking relativity and quantum mechanics by taking into account the existence of quintessence mass.

[0056] Hence, it is now possible to derive the relativistic equations for mass and in turn for space and time from the quintessential wave equation, thus deriving special relativity as a universal case of quantum mechanics and thus uniting special relativity and quantum mechanics. This now allows a further understanding of the nature of space-time.

[0057] The Space-Time Lattice

[0058] The understanding of the true nature of space-time and how it is formulated in three dimensions of real space is crucial. To simply assume that space-time exists, and thence not to question the nature of that existence, denies a deeper understanding of the universe.

[0059] In order to understand the nature of space-time itself, at the quantum level a further look at the nature light and the photon is necessary. Since Einstein's description of light as a particle (the photon) and the description of the photoelectric effect, the standard picture of light as simply a wave can, no longer be applied. If light was to exist as a photon, it could not exist in one dimension, as ordinary waves do, it would need to be three dimensional, with the addition of time. Let us suppose, in this case, that a photon is a three dimensional helical ringlet of light, travelling in the x vector, and spinning around the x-axis. Conventionally this ringlet has a radius; $r=\lambda/2\pi$. The ringlet itself would be vibrating in the y and z vectors. The vectors x, y and z would represent the photon, the substance of which, would be travelling in the x direction and oscillating in the y and z vectors, which would represent oscillatory energy. This in turn would allow it to act as a wave, and create oscillatory electromagnetic fields.

[0060] It is important to re-examine space-time itself in this light, this would have one directional vector with two vector dimensions of energy, one of capacitance and one of electrical permeability, thus accounting for the well known constants of free space; the permittivity of free space (ϵ_0) and the permeability of free space (μ_0) respectively. The vector dimension of direction x, would be the direction of travel and those "quintessences" travelling in an outwardly direction would account for none other than the expansion of the universe. Three of these quintessences would naturally constitute three dimensional visible space-time. These constituents of space-time would interact with the generations of the other vector dimensions reciprocally. Thus one quintessence would sweep out one vector of permeability and one vector of permittivity, through which the other two quintessences could travel, and vica versa, creating a three dimensional space-time lattice.

[0061] The permittivity of free space, (ϵ_0) which is equivalent to capacitance, would as with capacitance plates, be determined by the effective separation between quintessences. The permeability of free space (μ_0) is in fact a force, measured as $4\pi\times10^{-7}$ N/A^2, would result from the force produced by the vibration of quintessence and would be dependent on the density of quintessence. Hence these two parameters would be reciprocal and thus the product of these two would therefore be a constant, which is recognised as none other than the speed of light.

$$c = \frac{1}{\sqrt{\mu_0 \varepsilon_0}}$$

[0062] This space time lattice would in effect be created by quintessences travelling in all directions with a speed of c within the lattice. The quintessences of the space time lattice would in effect produce a non-static ether. A non-static ether is fully compatible with special and general relativity. Indeed such an ether explains how space time can be curved as in general relativity. Furthermore, the existence of a non-static ether, was espoused by Einstein in his University of Leyden lecture on general relativity of May 5, 1920. In Einstein's own words;

[0063] "According to the general theory of relativity space without ether is unthinkable."

[0064] Recent evidence from a number of sources now strongly support the presence of this non-static ether, in the form of quintessence. An editorial from a major journal states "combined with other observations such as those of distant Supernova, the QMAP results corroborate the prevailing theory of inflation with the twist that the Universe is only one third matter (both ordinary and dark) and two thirds quintessence, a form of energy possibly inherent in empty space".

[0065] If we take into account the existence of quintessence and as such a three dimensional space-time lattice, matter which is intrinsically made of constituents of charge would interact with this lattice to produce the effects of mass. Mass would be perceived as a result of matter (whose constituent particles appear to contain charge) interacting with this lattice directly due to the inhibition of motion by the lattice's electrical permeability and permittivity vectors, which would form the existence of complex space. These quintessences would in the direction in the y and z vectors produce small vibrations of the order of the Planck length (10^{-35} m), whilst passing through the vectors of permeability and permittivity, thus producing the effects of mass.

[0066] The vibration would endow quintessence itself a (non rest) mass m_q equivalent, to the minimal mass of:

$$m_q = h/c^2 = 7\times373\times10^{-51}\ \text{kg}\cdot\text{sec} \tag{1}$$

[0067] The presence and magnitude of Planck's constant (h) and especially the speed of light (c) is thus explained. Indeed, the speed of light

$$c = \frac{1}{\sqrt{\mu_0 \varepsilon_0}}$$

is not in itself a fundamental quantity.

[0068] As the energy equivalence formula is $E=mc^2$, the minimal mass of a single quintessence, would thus be the minimal mass, h/c^2, hence again:

$$m_q = h(\mu_0\epsilon_0) = h/c^2 = 7.373\times10^{-51}\ \text{kg}\cdot\text{sec} \tag{1b}$$

or

$$m_q c^2 = h \tag{1c}$$

[0069] It is postulated by general relativity that the shape of space time itself can be altered, indeed the presence of the space time lattice now allows this to be altered by altering the density of quintessence. It is further clear that if quintessences underly the structure of the space-time lattice, they may also underly the structure of matter itself.

[0070] With regards a single quintessence, this passing through an energy vector of the space-time lattice would appear as a vibrating string. In a similar way to string theory, the conglomeration of these quintessences would produce the constituents of ordinary matter. Thus the general equation for the number of quintessences (n_q) in an object of mass (m) would be

$$m/m_q = n_q$$

[0071] The mass of the electron (m_e) for example, would be directly determined by the number of quintessences in the electron, multiplied by the mass of quintessence.

[0072] Quintessence and Complex Space

[0073] Quintessence is postulated to constitute the fundamental nature of space-time. Three quintessences each travelling in their respective x vectors at 90° to each other would create three dimensional real space-time. These quintessences would in the direction in their respective y and z vectors produce small vibrations of the order of the Planck length (10^{-35} m), this would create the vector dimensions of permeability and permittivity. The result would give space-time 9 dimensions of space as in superstring theory. However, unlike superstring theory the six hidden dimensions would not be "curled up so as to be so small as to be invisible" these six dimensions would be present in complex space. Thus, only three of these dimensions would represent ordinary three dimensional particulate space time i.e. three dimensional objects. The other six dimensions produced by the vibrations of quintessence would form complex space.

[0074] The mathematics of complex space, using imaginary $\sqrt{-1}$ or (j) numbers, is assumed in the standard formulation of the Shrodinger wave equation. Thus the presence of complex space is an integral part of quantum mechanics.

$$-\frac{h^2}{2m}\cdot\frac{d^2\psi}{dx^2} + V\psi = jh\cdot\frac{d\psi}{dt}$$

[0075] The mathematics of complex space is also an essential and integral part of the principles and application of modern electronic and control engineering. Indeed it has been well recognised for some time that each direction vector in electronic engineering can, be associated with complex vectors.

[0076] As this complex space consists of the vectors of permittivity and permeability it would only be "felt" by charged particles as in the electron. Nevertheless, as all particles are fundamentally composed of charged particles the effects of complex space would be felt by endowing these particles with mass and in turn kinetic energy.

[0077] In conventional complex space, a 2 dimensional Cartesian Argand diagram is mathematically used. However, in order to formulate the equations for particles a three dimensional Argand diagram is essential. This will have three dimensional vectors, one real vector and two imaginary vectors. Three of these diagrams will be required to fully describe the nature of particles, each with a real vector in the x, y and z vectors, respectively. Nevertheless, in the instance below the real vector is the x vector and the two imaginary vectors are given by $({}_jy,{}_jz)$

[0078] The Three Dimensional Argand Diagram

[0079] The beauty of a three dimensional Argand diagram is that the complex conjugate (i.e. the mirror image which confers mathematical reality on the coordinates) is formed by the value of the minus coordinate in the other complex vector dimension. Thus the complex conjugate of $(C_x^{1/2}+{}_jc_y^{1/2}+{}_{-j}c_z^{1/2})$ is $(c_x^{1/2}+{}_jc_y^{1/2}+{}_jc_z^{1/2})$. These two sums when multiplied thus give a real number solution.

[0080] Furthermore it is clear that nine dimensions of space time are necessary in the general relativistic equations. By including complex space we thereby create the nine dimensional spacial metrictensor and the metric energy tensor of matter necessary for computations for general relativity From here we can begin to understand the true structure of matter.

[0081] Energy and the Space-Time Lattice

[0082] The presence of numerous experimental data for quantum tunnelling. and indeed the recent observations by Nicholas Gisin, on the entanglement of distant photons now returns us to EPR experiments.

[0083] Using the quintessential modification of the de Broglie wave equation, gives us an insight into these teleportation and EPR effects.

[0084] As

$$\lambda=hc/\beta E \tag{2}$$

and

$$E=hn_q \tag{1a}$$

then

$$\lambda=c/\beta n_q \tag{2b}$$

[0085] Importantly, as indicated by equation (2b), energy having no quintessence; would have a wavelength of infinity. Specifically pure energy containing no quintessences, would have a lambda of infinity. According to quantum mechanics an infinite wavelength would result in the probability of that energy being anywhere. As energy itself has no electrical charge it would not be impeded by the permittivity and permeability of the three dimensional space-time lattice. Moreover, energy would not be detectable in three dimensional space-time, unless it interacted with matter, as in the EPR experiments. Indeed, energy is not observed when not bound to any form of mass or particle. Thus equation 9d, takes us to our original assertion

[0086] Energy is Not Bound by the Space-Time Lattice

[0087] Thus, as the EPR experiments suggest the existence of energy separate from matter and thus separate from the three dimensional space-time lattice, it is interesting to find that experiment suggests the existence of free energy in a continuum separate from space time to produce the effects of quantum teleportation

[0088] This is not, however, teleportation across an additional dimension, this is a term to describe in partially familiar terms the dissociation of energy from the three dimensional space-time lattice. As time is inextricably linked to each dimension of space, the effects of energy would be inextricably linked to the events, such as the creation of virtual particles, we see interacting within space-time.

[0089] It is unlikely that observers have any direct day to day experience to explain quantum events. Nevertheless, quantum physics may have given us a window into the hitherto hidden workings of the Universe. Thereby, the mystery of the uniformity of the Universe, across distances which the speed of light could not apparently traverse, is readily explained by the fact that the free energy contained in the Universe is not bound by the space-time lattice.

[0090] In the case of light, due to the exceedingly small masses involved, there would be relatively easy exchange of matter with free energy within a photon. This would make the photon the ideal experimental tool to look for energy which is not bound by matter and in turn energy which is not bound in space-time. Indeed, very recently Furusawa et at. have reported to have observed the transference of energy as photons from A to B, without those photons traversing space-time. This finding which has been supported using other experimental techniques, is very important as it suggests the existence of such a quantum continuum.

[0091] We have already seen strong experimental data using photons, atomic spins and other data for quantum teleportation which have recently been published which support these findings. According to the above equations the teleportation would vary in a predictable fashion, as with photons, in line with the wavelength of the light used, relative to the size of vibration of quintessence. As regards matter, the results do confirm that the effect of quantum tunnelling is indeed dependant on the wavelength of matter and the size of that matter.

Part II—Particle Physics

[0092] Electron Structure

[0093] Understanding the electron is fundamental to the understanding of the elementary particles. The hidden nature of the electron may recently have been revealed through observations by Horst Stormer, Daniel Tsui and Robert Laughlin for which a Nobel prize has recently been awarded. They describe a quasi electron particle of charge ⅓e. This has been described on a quantum basis as a vortex of energy, bound as a quasi particle in one dimension x, but not bound in the other two dimensions y and z, allowing dispersion in space-time as a vortex. What is more intriguing are the experimental conditions in which this occurs. First of all a two dimensional electron gas is created and held between two capacitance plates. A magnetic force is then applied in the remaining dimension, virtually creating a one dimensional passage through which only a quasi electron appears to be able to pass.

[0094] Given the presence of charge of ⅓e, then three of these quasi electrons could form an entire electron in three dimensional visible space time. Nevertheless, each would have energy and hence a wave function which would be present in the other vectors. This electron could thus follow the probability functions as described by the Shrodinger wave equation for ψ (otherwise termed as "essence" by Shrodinger)

[0095] If the mass of the electron (m_e) is constituted from quintessence, using the formula:

$$m_e/m_q = n_q$$

[0096] Then an electron would be constituted from:

$$\frac{9.11 \times 10^{-3}\ \text{kg}}{7.373 \times 10^{-51}\ \text{kg} \cdot \text{sec}} = 1.235 \times 10^{20}\ \text{quintessences/sec.}$$

[0097] Thus taking into account the mass-energy content of quintessence (m_q) it is independently possible to derive the magnitude of the charge of an electron (e) using the following equation.

$$e = \sqrt{\frac{m_q \varepsilon_0}{\left(\frac{4}{3}\right)\pi hc}} = 1.61 \times 10^{-19} C$$

[0098] This is in close agreement with the experimentally observed charge on the electron of 1.602×10^{-19} C.

[0099] Interestingly substituting $m_q = h/3c^2$ in the above equation we have:

$$e = \sqrt{\frac{\varepsilon_0}{3\left(\frac{4}{3}\pi c^3\right)}} \tag{6}$$

[0100] This can also be written as

$$e = \sqrt{\frac{\varepsilon_0}{3\left(\frac{4}{3}\right)\pi c^3}} \tag{6a}$$

[0101] Equation (6) has a number of very special implications, if re-examined, firstly three of these quasi electron spheres appear to be required to constitute the charge of the electron. More intriguingly, it indicates that the charge is related to the volume of a sphere with an apparent radius of c. Thirdly it indicates that the square of the charge of an electron (e) is proportional to the permittivity of free space (so). The charge given from equation (3) is in close agreement with the measured charge of the electron. Furthermore a more exact value for the charge of the electron (to seven decimal places) can be deduced by taking into account the gravitational field of the Earth (see Gravity and the Charge of the Electron). Furthermore the charge of the electron (e) can now be derived from first principles. Thus, equation (3) corroborates the evidence that the electron is indeed composed of three quasi electrons in keeping with recent experimental findings.

[0102] The significance of the electron, composed of three spheres each with a radius of c, is not immediately clear, but can be understood if the frequency of rotation of the electron is taken into account. Thus if the diameter of the electron was approximately 10^{-19} m, then its spin would need to be

$$\frac{1}{c} \times 10^{-15}$$

m approx. eq. 10^6 cycles/sec. Thus given a very high rotation rate an electron could have an effective radius of 1/c and still occupy subatomic sizes. Indeed these observations might be used to estimate the rate of rotation of the quasi electron and its size (see Appendix 1).

[0103] With regards a single quintessence, this passing through an energy vector of the space-time lattice would appear as a vibrating string. In a similar way to string theory, the conglomeration of these quintessences would produce the constituents of ordinary matter. The electron, for example, would be constituted from approximately 1.235×10^{20} quintessences.

[0104] The dimensions of the equation for the electron can be readily resolved by considering each of the three vector dimensions. The exact dimensions of the equation need to be considered in the light of the nature of space-time itself. These dimensional equations help explain the nature of matter. Indeed the equation for the electron may be necessary for the full understanding of gravity

[0105] Complex Space and Electron Structure

[0106] The presence of complex space also now further explains the conformation of the electron, and its formulation at the quantum level, and the presence of particles, anti-particles and their spin up and spin down characteristics.

[0107] Indeed the short form equation for the charge of the electron (−e) can now be rewritten as a metric tensor with three dimensions in real space and six in complex space.

[0108] Thus if three of the x, y and z vectors are in real space and six vectors in complex space, where c is the speed of light in the real space vector, $_{j}c$ is the speed of light in the complex vector and $_{-j}c$ is the complex conjugate of $_{j}c$, thus the electron can be mathematically represented by the equation:

$$-e = \varepsilon_{qe} \Big/ \left(\frac{4}{3}\pi\right)^{1/2} \cdot \begin{matrix} (c_x)^{1/2} \cdot (jc_y)^{1/2} \cdot (-jc_z)^{1/2} \\ + \quad + \quad + \\ (-jc_x)^{1/2} \cdot (c_y)^{1/2} \cdot (jc_z)^{1/2} \\ + \quad + \quad + \\ (jc_x)^{1/2} \cdot (jc_y)^{1/2} \cdot (c_z)^{1/2} \end{matrix}$$

[0109] Which now elegantly gives the real number solution

$$e = \frac{\varepsilon_{qe}}{3\sqrt{\left(\frac{4}{3}\right)\pi c^3}}$$

[0110] Where e=ϵ_{qe} is given as the permittivity of free space for a single quasi electron Equation 4 represents a "complex" tensor

[0111] Whilst the two dimensional Argand diagram has four quadrants, the three dimensional Argand diagram has eight cubic sectors. Two of these cubic sectors are diametric opposites and can represent "real" particulate objects. These have the primary coordinates x, y, −z; as in the electron described above, and the −x, −y, z, with the real vector x now having a minus sign. These two "real" cubic sectors, therefore, mathematically represent particles and their anti-particles.

[0112] The mathematical presence of the two primary diagonal mirror images (x, y, −z and −x, −y, z) now allow the introduction of the concept of antiparticles. This extension of the maths into a three dimensional Argand diagram thus results in the automatic formulation of the maths of antiparticles. Thus the charge of the positron ($^{+}$e) is formulated by the shortened form equation, where the real vectors now each have the minus sign, and therefore exist in the −x, −y, z sector of the three dimensional Argand diagram.

$$e = \varepsilon_{qe} \Big/ \left(\frac{4}{3}\pi\right)^{1/2} \cdot \begin{matrix} -c_x^{1/2} \cdot_{-j} c_y^{1/2} \cdot_{j} c_z^{1/2} \\ {}_{j}c_x^{1/2} \cdot -c^{1/2y} \cdot_{-j} c_z^{1/2} \\ {}_{-j}c_x^{1/2} \cdot jc_y^{1/2} \cdot -c_z^{1/2} \end{matrix}$$

[0113] The three dimensional Argand diagram also accounts for chirality and indeed the up and down spin of the electron. There are two other "real" primary coordinates in the Argand diagram, these are themselves the partial mirror images of the above coordinates (i.e. x, −y, z and −x, y, −z). In particular the y axis is of the opposite sign, thus in particles the y axis is in the downward direction, to form down spin particles and in anti-particles in the up direction, to form the antiparticle The up spin electron is given by eq. 8 and hence the down spin electron (−e|↓≦) is given by the equation

$$-el\downarrow\rangle = \varepsilon_{qe} \Big/ \left(\frac{4}{3}\pi\right)^{1/2} \cdot \begin{matrix} c_x^{1/2} \cdot_{-j} c_y^{1/2} \cdot_{j} c_z^{1/2} \\ {}_{j}c_x^{1/2} \cdot c^{1/2y} \cdot_{-j} c_z^{1/2} \\ {}_{-j}c_x^{1/2} \cdot jc_y^{1/2} \cdot -c_z^{1/2} \end{matrix} \tag{9}$$

[0114] Thus the three dimensional Argand diagram accounts directly for the presence of antiparticles and the spin up and spin down particles seen in nature. It also accounts for the necessity of the electron to form a square root spherical object, as complex space depends on √−1, otherwise known as j.

[0115] Electron Pairing and Superconductivity

[0116] As the quintessences making up the electron are in a square root conformation, each of these quasi electrons would have a tendancy to pair to form an entire sphere.

[0117] The square root sphere structure of electrons with up and down spins can now superimpose to produce a complete sphere of varying extents. This produces electron pairing as seen at the atomic and molecular levels. It also accounts for the Pauli exclusion principle. This pairing thus accounts for the reactivity of the valence electrons and the electron probability densities, which in turn accounts for the existence of chemistry.

[0118] Furthermore, it is possible to account directly for superconductivity from first principles. For if both the complex and real vectors of the electron combine completely, the product of an up and down spin electron form a perfect superimposed sphere with radius c, with a charge of 2.59×10^{-38} C, denoted by the formula:

$$e^2 = \frac{\varepsilon o}{3\left(\frac{4}{3}\pi c^3\right)} = 2.59\times10^{-38}C \tag{6b}$$

[0119] As with standard superconducting theory, superconductivity can be explained by the formation of "Cooper" electron pairs, where the electrons are forced to pair by the presence of positive crystal charge in particular formation, at supercooled temperatures. In addition the electron pair now forms a stable entity whose angular momentum cancels.

[0120] It additionally becomes clear that the charge of two separate electrons (2e) is 3.2×10^{-19} C, but the charge of the combined electrons (e^2) is 2.59×10^{-38} C. This electron pair thus appears to have 19 orders of magnitude less charge than the electron and in turn 19 orders of magnitude less resistance. It is this effective reduction in charge and in turn resistance, which may account for superconductivity. When observed directly any electrical interaction with the Cooper electron pair will, however, result in the release of the full charge of both electrons, so that the full electrical charge put in will be equal to that coming out of the apparatus.

[0121] The Fine Structure Constant

[0122] Intruiginty from our knowledge of the electron we can further define the term .alpha., the fine structure constant; from the structure of the electron. Thus as the standard term

$$\alpha = \frac{e^2}{hc\times 47\pi\varepsilon_0};$$

substituting the term

$$e^2 = \frac{\varepsilon_0}{3(4/3)\pi c^3} \tag{eq. 6}$$

and

$$h = m_q c^2 \tag{eq. 1}$$

we find:

$$\frac{2\pi}{\alpha} = m_q[3(4/3\pi c^3)]^2$$

*or

$$\frac{2\pi}{\alpha} = \frac{m_q e^4}{\varepsilon_0^2}$$

[0123] For brevity we may represent the quasi electron structure as $(4/3)\pi c^3=\theta$; to signify its threefold symmetry, thus

$$\frac{2\pi}{\alpha} = m_q(3\theta)^2 \tag{10}$$

[0124] Indicating that the fine structure constant of the electron (a) is indeed related to its dimensional structure. Again taking into account the effects of gravity the fine structure constant can be derived from first principles to nine decimal places (see Gravity and the Charge of the Electron).

[0125] Fundamental Forces and Particle Structure

[0126] In order to understand the fundamental forces and the nature of fundamental particles, an overview is required. Thus, there are three major forces; strong, electro-weak and gravity, each mediated by three force particles the gluon, photon and graviton respectively. These in turn, influence three types of particle, the quark, lepton, and by general relativity space-time itself. Each of these are composed of particles with multiples of charge of ⅓, which are themselves in three generations, and are present in three dimensions of real space. It is important that a comprehensive view of nature explains this threefold symmetry.

[0127] Using the Standard Model of particles, it is well accepted there exist quark particle charges of −⅓, −⅔ and +⅓ and +⅔ in quarks and anti-quarks. Given that each particle is made up of three quarks the presence of these fractional charges support the association of the fractional charges in this way to form three dimensional charged particles. In stable particles each of the three quarks would have a vector in one dimension, giving the three quarks together an existence in three dimensional visible space time. The particles that bind the quarks (gluons) are themselves required, in stable particles, to have three different color charges, one color in each dimension, for the particle to exist in three dimensional space-time. Furthermore, there are three generations of quarks (and indeed leptons).

[0128] The Standard Model (or a modification of this) and in particular the observation of quarks and indeed quasi electrons with fractional charge of ⅓ and ⅔ in both cases, indicates that particles are constituted from the equivalent of three of these quasi particles to form an electron and quarks to form baryons. In the normal three dimensions the energy would be carried by the particle, However, because each particle is constituted of three quasi particles and in each quasi particle or quark one visible dimension would be the direction vector, in the other two hidden dimensions of each vector the waves would carry energy. Thus each particle would be associated with vibration, which would account for wave particle duality and Heisenberg's uncertainty principle in three dimensional visible space-time.

[0129] These observations lead us directly to the previous postulate that the structure of the electron is composed of none other than three (root) spheres, and that this equation for the electron allows the determination of the charge of the electron from first principles, thus:

$$e = \frac{\varepsilon 0^2}{[3(4/3\pi c^3)]} \tag{6}$$

[0130] In addition the mass of the proton (m_p) can be directly calculated from the ratio of the mass (m_e) of the electron, given by the equation:

$$\frac{m_e}{m_p} = 5.45 \times 10^{-4} = 3\frac{\pi}{\sqrt{c}} \tag{11}$$

[0131] Strictly we should write,

$$\frac{m_e}{m_p + m_e} = 3\pi\sqrt{c};$$

which is much more elegant.

[0132] Which now gives

$$\frac{m_e}{m_p} = \frac{1}{\sqrt{c}/3\pi - 1} = 5.4462 \times 10^{-3}$$

[0133] This is in very close agreement with the experimentally derived ratio of the proton to electron masses which is also; 5.4462×10^{-3}

[0134] Thus the correlation factor between theory and experiment has a maximum error <0.00001.

[0135] If we combine equation 3:

$$e = \sqrt{\frac{\varepsilon_0}{3(4/3)\pi c^3}}$$

and equation 13:

$$\frac{m_e}{m_p} = 3\frac{\pi}{\sqrt{c}}$$

the positive charge of the proton (e_p) is given by:

$$e_p = \sqrt{\frac{\varepsilon_0}{3(4/3)\pi c^3}} \times m_e \times 3\frac{\pi/\sqrt{c}}{m_p} = e \tag{12}$$

[0136] The stable nuclear proton conformation can thus be represented by the short form equation:

$$p=3^{+}\sqrt{3(4/3)\pi c^3}\times 3(\pi/\sqrt{c}) \tag{13}$$

[0137] This forms a stable 3×3 conformation as with the stable electron structure.

[0138] Importantly the term ($\pi/\sqrt{c}$) is the 90° solution to the Shrodinger wave equation for an electron confined in a space with radius c!.

[0139] Thus the standard equation for an electron confined in a one dimensional box is given by:

$$E\psi(x) = -\frac{h^2}{2m}\frac{d^2\psi(x)}{dx^2}$$

[0140] If the one dimensional box has a length 2L the quantum amplitude (A) can only be non zero between x=0 and X=2L and the standard solution for the amplitude is none other than:

$$A=(1/L^{1/2})$$

[0141] Thus in one dimension the standard solution to the Shrodinger wave equation is:

$$\psi(x)=(\pi/L^{1/2})\mathrm{Sin}\ x/L$$

[0142] Thus not only is the electron charge derived from the equation for three spheres each with a radius of c (eq. 3); but the proton mass and charge can also be derived from the standard solution to the Shrodinger wave equation for a an electron confined in a space of radius c!.

[0143] The term ($\pi/c^{1/2}$) itself would thus most logically represent the gluon which is present in the proton. These gluons would bind the quasi electrons together to form the fundamental particles

[0144] The masses of all the known particles, including the up and down quarks, the W boson, the muon, charm, strange, the tauon, truth and beauty can thus also be derived from first principles in this fashion, and have the quasi electron as their basic constituent particle (see Appendix 1).

[0145] Thus the structure of the muon (μ) can also be derived from the ratio of the mass of the electron (m_e) and the mass of the muon (m_μ):

$$m_e/m_\mu=4.7\times10^{-3}=c^{1/3}$$

Thus

$$\mu=\epsilon_0{}^{1/2}\times m_e/m_\mu\times3^{-}(4/3=\pi c^3)^{1/2}\times(\pi/c^{1/3})$$

[0146] Where the charge of the muon is in this equation equivalent to that of the electron e. In this case ($\pi/c^{1/3}$) can be considered to represent a specific high energy photon. Thus the structure of the muon, written in short form is:

$$\mu=3^{-}(4/3\pi c^3)^{1/2}\times(\pi/c^{1/3}). \tag{14}$$

[0147] Moreover the structure of the tauon can be calculated from the ratio of the mass of the electron and that of the Tauon (1.79 Mev);

[0148] Thus

0.511 Mev/1.79 Gev=2.85×10^{-4}

$$m_e/m_r=(\pi/c)^{1/3}\times(\pi/c)^{1/9}=2.85\times10^{-4}$$

[0149] As the charge of the tauon is equivalent to the charge of the electron, hence the structure of the Tauon is given by the above equation

$$e_\tau=\epsilon_{qe}\times(m_e/m_\tau)\times3^{-}(4/3\pi c^3)^{1/2}\times(\pi/c)^{1/3}\times(\pi/c)^{1/9}=e$$

[0150] This equation accurately predicts the charge −1; and mass of the Tauon (.~1.78 Gev). Thus the structure of the Tauon can in short form be given by the equation

$$\tau=-3(4/3\pi c^3)^{1/2}\times(\pi/c)^{1/3}\times(\pi/c)^{1/9} \tag{15}$$

[0151] Furthermore a more exact value for the mass of the muon and tauon can be deduced by taking into account the gravitational field of the Earth in a similar way to identifying the exact charge of the electron. In addition it may be necessary to take into account a possible mass value of the neutrino to arrive at a precisely accurate mass value of the muon and tauon. Nevertheless, the mathematical proof of these short form equations lies in the fact that they can very closely identify the charge and the masses of these particles, from first principles, as in equations.

[0152] Overall the mathematical geometrical structure of all the particles can be derived from the quasi electron, which is in turn derived from quintessence. Thus, the short form particle structures can now be derived from first principles. This includes the quasi electron (qe) and electron (e), from which the quarks (u,d) and in turn the stable proton (p) and stable neutron (n) and alpha particle (a) respectively are derived. The general structure of the force carrying bosons the photon. (g) and the gluon (γ) and the intermediate vector boson (W) can be given. It will also intriguingly be possible to derive, according to their generation, the structure of the strange (s) charm (c), beauty (b, or bottom) and truth (t or top) quarks directly from the structure of the muon (μ) and Tauon (τ) respectively.

[0153] Using the term $\Theta=(4/3\pi c^3)$, where, −/+ represents the charge of the quasi electron, we find:

[0154] 1st Generation:

$$(q_e)={}^{-}\Theta^{1/2} \tag{6c}$$

$$e=3^{-1/2} \tag{6}$$

$$d={}^{-}\Theta^{1/2}\cdot3(\pi/c^{1/2}) \tag{16}$$

$$u=2^{+}\Theta^{1/2}\cdot3(\pi/c^{1/2}) \tag{17}$$

$$s={}^{-}\Theta^{1/2}\cdot3(\pi/c^{1/2}) \tag{18}$$

[0155] 2nd Generation

$$\mu=3^{-}\Theta^{1/2}\cdot(\pi/c^{1/3}) \tag{14}$$

$$c=2^{+}\Theta^{1/2}\cdot(\pi/c^{1/3})\cdot(\pi/c^{1/4}) \tag{19}$$

$$b={}^{-}\Theta^{1/2}\cdot(\pi/c^{1/9})\cdot(\pi/c)^{1/4} \tag{20}$$

[0156] 3rd Generation

$$\tau=3^{-}\Theta^{1/2}\cdot(\pi/c)^{1/3}\cdot(\pi/c)^{1/9} \tag{15}$$

$$t=2^{+}\Theta^{1/2}\cdot(\pi/c)^{1/3}\cdot(\pi/c)^{1/9}\cdot(\pi/c)^{1/4} \tag{21}$$

[0157] Particle Gluons (g):

$$g_1=(\pi/c^{1/2}) \tag{22}$$

$$g_2=(\pi/c)^{1/2} \tag{22a}$$

$$g_3=(\pi/c^{1/4}) \tag{22b}$$

$$g_4=(\pi/c)^{1/4} \tag{22c}$$

[0158] Particle Photons (.gamma.):

$$\gamma_1=(\pi/c^{1/3}) \tag{23}$$

$$\gamma_2=(\pi/c)^{1/3} \tag{23a}$$

$$\gamma_3=(\pi/c^{1/9}) \tag{23b}$$

$$\gamma_4=(\pi/c)^{1/9} \tag{23c}$$

[0159] Intermediate Vector Boson ($W^{+/-}$):

$$W^{+}=3^{+}\Theta^{1/2}\cdot 2(\pi/c^{1/6})^{6} \tag{24}$$

$$W^{-}=3^{-}\Theta^{1/2}\cdot 2(\pi/c^{1/6})^{6} \tag{25}$$

[0160] Stable* Proton:

$$p=3^{+}\Theta^{1/2}\cdot 3(\pi/c^{1/2}) \tag{13}$$

[0161] Stable* Neutron:

Stable * Neutron:

$$n = \begin{array}{l} {}^{+}\Theta\downarrow^{1/2}\cdot 2(3\pi/c^{1/2})\cdot{}^{-}\Theta\uparrow^{1/2} \\ {}^{+}\Theta\downarrow^{1/2}\cdot 2(3\pi/c^{1/2})\cdot{}^{-}\Theta\uparrow^{1/2} \\ {}^{+}\Theta\downarrow^{1/2}\cdot 2(3\pi/c^{1/2})\cdot{}^{-}\Theta\uparrow^{1/2} \end{array}$$

* Stable nucleonic neutron and proton conformations differ slightly from the Standard Model, this is due to the sharing of quasi electron and quasi positron particles within the nucleus, which allows stabalisation of these particles by the formation of stable 3×3 structures. The Standard conformations which describe non-nucleonic neutrons and protons are additionally given in Appendix 1.

[0162] Alpha particle (α):

$$\text{Alpha particle }(\alpha) := \alpha = \begin{array}{l} [3^{+}\Theta]\downarrow^{1/2}\cdot 2(3\pi/c^{1/2})\cdot[3^{-}\Theta]\uparrow^{1/2} \\ [3^{+}\Theta]\uparrow^{1/2}\cdot 2(3\pi/c^{1/2})\cdot[3^{-}\Theta]\downarrow^{1/2} \\ [3^{+}\Theta]\downarrow^{1/2}\cdot 2(3\pi/c^{1/2})\cdot[3^{-}\Theta]\uparrow^{1/2} \end{array} \tag{27}$$

[0163] The mathematical proof for these structures and their decay mechanisms is lengthy and is thus fully contained in Appendix 1. All the particle structures are accurately mathematically defined by the masses of these particles.

[0164] The structure of these particles all contain the quasi electron and thus the metric tensor structure necessary in the formulation of the gravitational equations is sustained. The respective forces created by the gluon and the photon are important as they tell us the behaviour of matter and also lead to the likely structure of the graviton

[0165] Particle Spin and Size

[0166] The significance of the electron, composed of three spheres each with a radius of 1/c, is not immediately clear, but can be understood if the frequency of rotation of the electron is also taken into account. Knowing the structure of the electron has led us to deduce its charge and thus may lead us estimate its size and spin. Thus these observations might be used to calculate the radius and rate of rotation of the electron.

[0167] Let us suppose, that nature is truly beautiful, and that the radius of the fundamental quasi electron is indeed 1/c, and in turn the radius was balanced by the velocity of rotation 2π/c. This can be directly confirmed mathematically by taking into account the known spin of the electron, h/4π. Thus the actual spin of the electron may be calculated form the known energy of the spin.

[0168] The radius of the electron is not up till now known, but the radius of a quark has been estimated, and this is the radius derived from deep inelastic collisions of the proton. These estimates reveal a radius of approx. $r_p=1.18\times10^{-15}$ m This value may be used to assist in confirming the spin of the proton in revolutions per sec. (revs) and in turn the spin and size of the electron. Firstly we may proceed to estimate the spin of the proton. Thus as h=E·t (Joules×sec) and h=E·t=F·d·t (Joules×sec), then the spin;

$$h/4\pi=F\cdot d\cdot t \tag{28}$$

[0169] As F=ma, where $\alpha=(\text{revs}\cdot 2\pi)^2 r_p$ and m=the mass of the proton, then

$$h/4\pi=m(revs\cdot 2\pi)^2 r_p\cdot d\cdot t$$

[0170] The actual distance (d) traveled in a circle of half integer spin in 1 second is: $\text{revs}\cdot\pi r_p$ thus:

$$h/4=m(revs\cdot 2\pi)^3 r_p^{\,2}/2$$

[0171] Hence:

$$revs=[h/m(2\pi)^4 r_p^{\,2}]^{1/3}$$

[0172] Taking the effective mass the proton as 1.6726×10^{-27} kg, then the rate of spin of the proton in revolutions/sec is:

$$revs=5.65\times10^{6}\text{ cycles/sec}$$

[0173] From the frequency of the specific rotation of the proton, given the half integer spin associated with the proton, we can thus mathematically confirm the relationship between the radius of a particle and its spin:

$$r_p\times revs/2=1/c \tag{29}$$

[0174] Furthermore, the fundamental radius of 1/c seen in geometric structure the quasi electron, is also reflected in the rotation rate and radius for the proton, thus as above 1/c÷½ revs=1.85×10^{-15} m. Moreover, this means the actual half integer velocity of rotation is none other than 2π/c in metres/sec. So that the particle is in harmonic balance.

[0175] Using the fundamental formula h/4π=F·d·t, it is possible to obtain accurate estimates of the radius and spin rates of the electron, or indeed any particle, using the same principle of harmonic balance. Using the formula:

$$revs=[h/m(2\pi)^4 r_e^{\,2}]^{1/3}$$

[0176] It appears there are two unknowns, the radius if the electron and its revolution rate, however, in accordance with the equation, r_p=2/c.revs, which gives the revolution rate of the proton, the same principle may also be used for the electron, by substituting r_e=2/c.revs, such that:

$$revs=hc^2/4m_e(2\pi)^4 \tag{30}$$

[0177] Taking the mass of the electron 9.109382×10^{-31} kg, the rate of revolution of the electron is:

$$revs=1.048\times10^{10}\text{ cycles/sec}$$

[0178] Which gives a predicted radius of the electron as

$$r_e=6.336\times10^{-19}\text{ cycles/sec}$$

[0179] So the half integer rotation velocity (revs.πr) is 2π/c !, for the electron in keeping with the harmonic balance of the electron.

[0180] The same principle may be used to obtain an accurate estimate of the spin and radius of the muon, or any other particle. Using the above formula

$$revs=hc^2/4m_e(2\pi)^4 \tag{31}$$

[0181] Then as the mass of the muon is 1.8823×10^{-28} kg then the revs of the muon $f_\mu=5.070\times10^{-7}$ cycles/sec and the radius r_μ is thus 1.316×10^{-16} m.

[0182] It is now possible to begin to explain how the muon and the other subatomic particles are formed. If a quasi electron is complexed with another structure the total geometric structure needs to maintain harmonic balance. So the frequency of rotation would need to match geometric structure with which the quasi electron was complexed

[0183] Intriguingly we find asymptotic convergence for the formulas for frequency and mass occurs, when the geometric structure complexed with the quasi electron has the structure represented by ($\pi/c^{1/3}$) [giving the frequency divided by two, because the single integer spin of the force carrying particles compares to a half integer spin for the muon]. So that

$$(f_r3\pi/2)^{1/3}=f_\mu$$

[0184] When the ratio of the masses of the electron (m_e) and muon (m_μ) are related, such that:

$$m_e(3\pi/c^{1/3})=m_\mu$$

[0185] Indeed we find that (allowing for the neutrino) this ratio is very close to the actual ratio of the mass of the electron to the mass of the muon, determined experimentally.

[0186] Furthermore, we have seen that these geometric structures, representing harmonics of the speed of light, which either match the frequency or the amplitude of vibration of the quasi electron, mathematically define the masses of the particles and the fundamental forces of Nature.

Part III—Quantum Gravity

[0187] Quantum General Relativity

[0188] Given the overall energy "complex" energy tensor structure of the electron and the metric tensor, assumed in general relativity, the quantum nature of gravity itself can now be explored. The spherical complex tensor for the electron and the positron give the mathematical quantum structure and energy tensor for all the other particles. Together with the time dimension these nine space dimensions account for the 10 parameters present in the metric tensor necessary to formulate the equations for gravity using Riemann geometry and thus forms the basis of quantum gravity. Intriguingly the metric tensor at each point in space time is required to consist of a collection of ten numbers, Consequently, ten dimensional space-time hypotheses, such as this or superstring theory, do automatically yield general relativity.

[0189] Furthermore, the mathematical representation of the graviton and the gravitational constant may be directly estimated from the knowledge of the mass and radius of quintessence. Thence, the force of the vibrations of quintessence lead directly to quantum gravity.

[0190] The radius of quintessence should be approximately in keeping with the Planck length estimate (r), which is conventionally derived from the standard dimensional equation:

$$r_q^2\cong Gh/c^3 \tag{32}$$

[0191] Given the nine spacial parameters present in the metric tensor, used in general relativity we find that the actual formula for r_q^2 is mathematically in agreement with theory when:

$$9r_q^2=Gh/c^3 \tag{33}$$

[0192] This again supports the 9 dimensional view of space and the size of the vibrations of quintessence can thus be estimated.

$$r_q=1.35\times10^{-35}\text{ m} \tag{33a}$$

[0193] This value is in agreement with the Planck length. Indeed if the above equation is correct then we find that we can derive the standard equation for the general relativistic increase in radius, r', (eq. 34) directly from first principles and arrive at a more fundamental equation for quantum gravity. As

$$r'=G\cdot M/3c^3 \tag{34}$$

[0194] By substituting eq. 33) into equation 34, a fundamental relationship between r' and M is obtained.

$$r'/3r_q^2=GMc^3/Ghc^3=Mc/h$$

[0195] And substituting the quintessential equation, $h=m^qc^2$ (eq. 1) then:

$$r'/3r_q^2=M/m_qc=n_q/c \tag{35}$$

[0196] Hence the ratio of the change in radius to that of the radius of quintessence squared, is proportional, by a factor of c, to the ratio of the mass M of an object to that of the mass of quintessence, effectively the number of quintessences. Thus the change in radius, r' due to gravitation, is related to none other than the ratio of the mass and radius of an object to the mass and the square of the radius of quintessence. Thus again the gravitational change in radius is directly related to the number of quintessences.

[0197] Naturally, this would be exactly what would be logically expected if quintessence, like the equation for the charge of the electron (eq. 6) forms from a root sphere. Thus the change in spacial radius of a normal sphere is dependant on the square of the quintessential radius.

[0198] This increase in apparent radius represents none other than the (gravitational) binding energy for quintessence.

[0199] The meaning of the above dimensional equation (33) might itself be further understood by substituting the mass of quintessence (where $m_q=h/c^2$) into the equation. Thus in nine dimensions the gravitational constant (G) may be more logically given as,

$$9(\pi r_q^2/m_q)=G\pi/c \tag{36}$$

[0200] Where πr_q^2 is the cross sectional area of quintessence and m_q is the effective mass of quintessence, and thus

($\pi r_q^2/m_q$) represents the effective mass per unit area which quintessence exerts. This equation reduces to:

$$9r_q^2/m_q=G/c \tag{37}$$

[0201] From this we may derive the standard general relativistic relationship for the apparent change in radius (r') around a mass (M), from an understanding of the mass m_q and number (n_q) of quintessences. As $m_q=M/n_q$, then:

$$3r_q^2=G\cdot M/3c\cdot n_q \tag{38}$$

[0202] Then if

$$n_q=r'c/3r_q^2 \tag{39}$$

[0203] thus directly substituting for n_q in eq. 38:

$$r'=G\cdot M/3c^2 \tag{34}$$

[0204] The importance of this is that the gravitational change in radius now logically derives from equation 36, which describes the gravitational force as resulting directly from the mass of quintessence exerted/per unit area of quintessence.

$$9(\pi r_q^2/m_q)=G\cdot\pi/c \tag{36}$$

[0205] Thus equation 34 is the conventional equation for the general relativistic increase in radius (r') in a gravitational field, which is here derived from the underlying nature of quintessence. Thus the gravitational constant is derived from the mass and radius of vibration squared of quintessence from first principles.

[0206] Indeed it is apparent that a more fundamental equation for gravitation now exists, for equation (39) is mathematically accurate and numerically agrees with eq. 34:

$$r'/3r_q^2=n_q/c \tag{39}$$

[0207] These equations may be readily mathematically verified. If in accordance with standard general relativity, the apparent increase in radius r' is:

$$r'=GM/3c^2 \tag{34}$$

[0208] Then given that the mass of the Earth is 5.9745×10^{24} kg;

$$r'=1.478\times10^{-3}\text{ m}$$

[0209] Accordingly if $r'=3r_q^2\cdot n_q/c$; (eq. 39). Given the number of quintessences n_q constituting the Earth is M_E/m_q, then

$$n_q=5.9745\times10^{24}/7.3725\times10^{-5}=8.104\times10^{74}$$

[0210] As $r_q^2=1.823\times10^{-70}$ (eq. 33a) then:

$$r'=1.478\times10^{-3}\text{ m}$$

[0211] Thus equation 39 gives the same answer as the standard equation and may be understood on a logical basis. Indeed the meaning of c in the equation may be understood as it has been previously shown as being the basis for the radius of matter (eq. 6). Hence the general relativistic change in radius, r', is none other than the effective binding energy for quintessence.

[0212] Quantum Gravity and Wave Particle Duality

[0213] Quantum gravity can now be readily linked with quantum mechanics, indeed any observations which are self consistent must be able to do so easily.

[0214] The frequency of light has been previously derived

$$f=E/h=n_q$$

[0215] Thus the formula for the frequency of light (E=hf) has previously been explained theoretically by the simple observation that the frequency is determined quite directly from the number of quintessences (n_q) within the photon. The same principle has also been shown to apply to matter.

[0216] Let us now follow these equations for matter by calculating the wavelength of a photon from the Gravitational constant as an example; and also as a test of these observations and to demonstrate that the gravitational equations can also apply to the quantum world.

[0217] If

$$n_q=r'c/3r_q^2 \tag{39a}$$

[0218] where r' is the general relativistic increase in radius, and r_q is the radius of quintessence (eq. 33). Where $f=E/h=n_q$, substituting for n_q, then the frequency of the photon f_γ(where β=1) is given by:

$$f_\gamma=r'c/3r_q^2$$

[0219] Using the standard equation, $r'=GM/3c^2$ (eq. 34); we may substitute for r', thus we have:

$$f_\gamma = GM/9r_q^2c\ 15\text{ Thus}$$

$$f_\gamma = \frac{G}{9r_q^2c^3}\cdot m_\gamma c^2 \text{ and as } E = m_\gamma c^2;$$

$$f_\gamma = \frac{GE}{9r_q^2c^3} \tag{40}$$

Indeed as $9r_q^2 = Gh/c^3$, then $f_\gamma = E/h = n_q$

[0220] It is possible to also demonstrate that the same relationship holds for the wave equation for matter. If we take the relativistic wave energy of matter, which has been previously derived,

$$f=\beta^2n_q$$

[0221] This includes the term for the number of quintessences flowing through the electron, in the complex vectors of space-time, to give the relativistic electron momentum (p) and a term for the rest mass, thus substituting into (40)

$$f_\gamma = \frac{GE}{9r_q^2c^3} \tag{40}$$

[0222] As $f=\beta^2n_q$ for matter then the equation expands to:

$$f_m = \frac{G}{9r_q^2c^3}\cdot\beta^2E \text{ As } \lambda = v/f\text{, then}$$

$$\lambda = \frac{9r_q^2c^3v}{G\beta^2E} \tag{41}$$

[0223] Then the equation again reduces to:

$$G = \frac{9r_q^2c^4}{\lambda\beta E} \tag{3}$$

[0224] Equations 3, 40 and 41 are important as they show that the quantum wavelength of any particle of rest mass m can be derived from the gravitational constant G. Thus linking quantum mechanics to quantum gravity.

[0225] It is therefore important to confirm the numerical accuracy of the above equation (40). We can do this by comparing the result to the standard computation of the de Broglie equation, in a range where de Broglie itself is likely to be most accurate; which according to these observations is in the low energy range (see section on Wave Particle Duality).

[0226] If we take an electron with an energy of 0.1 KeV the wavelength is conventionally given (where the kinetic energy of the electron E_k is given by the product of the charge of the electron (C) and the potential applied eV=0.1 Kev), by the standard equation:

$$\lambda = h/p = h/(E_k \cdot 2m_0)^{1/2} \text{ thus}$$

$$\lambda = 6.63\times10^{-34}/[1.602\times10^{-19}\times1\times10^2\times18.22\times10^{-31}]^{1/2}$$

$$\text{hence}$$

$$\lambda \cong 1.23\times10^{-10}m \text{ Using}$$

$$\lambda = \frac{9r_q^2c^4}{G\beta E} \text{ Where } E = \gamma m_0c^2 \tag{3a}$$

[0227] At 0.1 Kev, electron velocity is 6×10^6 r/sec, thus $\beta=2\times10^{-2}$ and $\gamma=1/(1-v^2/c^2)^{1/2}=1.0002$. Thus:

$$\gamma = \frac{9\times1.82\times10^{-70}\times80.78\times10^{32}}{6.76\times10^{-11}\times\beta\times1.0002\times9.11\times10^{-31}\times8.998\times10^{16}}$$

$$\lambda = 1.21\times10^{-10}m$$

[0228] Divergence between the de Broglie equation and the above equation (2) occurs at intermediate and high energies where it is generally accepted that the standard de Broglie equation may be less accurate. The values for eq. 2 and de Broglie are compared to recent experiments, which demonstrate a relativistic curvilinear plot for wavelengths of matter in keeping with eq. 40.

[0229] The de Broglie equation in the non-relativistic format yields a simple log/linear scale, which is not in keeping with relativity; whereas eq. 3 is dependent on relativity and mathematically accounts for both relativity in calculating the wavelength. Indeed recent experiment on quantum tunnelling through a wire mesh strongly suggests that the relationship between energy and wavelength is relativistically curvilinear(ref 1). Furthermore equation 3a suggests a fundamental relationship between energy (E), relative velocity (v/c=.β), gravity (G) and the quantum wavelength (λ)

$$\lambda = \frac{9r_q^2c^4}{G\beta E} \text{ Indeed as } {}^9r_q^2 = Gh/c^3\text{, then} \tag{3a}$$

$$\lambda = hc/\beta E \tag{2}$$

[0230] Equation 2 is the very same as the Universal wave equation derived form first principles for the wavelength of tight and matter, which allowed a relativistic solution to the equations for wave particle duality (see Wave Particle Duality). This now indicates that these quintessential equations are compatible with relativity, quantum mechanics and quantum gravity.

[0231] Graviton Structure

[0232] From these observations, if the value for the gravitational constant is substituted into the equation (35) we may now estimate the probable geometric structure of the gravitation, which is the force particle mediating gravity by acting on quintessence. Thus the Gravitational constant has been previously derived from the vibration of quintessence by the equation:

$$G\cdot(\pi/c)=9(\pi r_q^2/m_q) \tag{36}$$

[0233] This is in accurate agreement with the value for $G(6.67\times10^{-11}\text{ N m}^2\text{ kg}^{-2})$. This suggests that the most probable mathematical representation of the graviton (φ), the third force carrying particle is

$$\phi=(\pi/c) \tag{42}$$

[0234] Thus the gravitational constant (G) can be given by the mass and radius of quintessence and the structure of the graviton

$$G=9\pi r_q^2/\phi m_q \tag{43}$$

[0235] This shows the gravitational force to be related to the fundamental radius of quintessence space time, and the graviton.

[0236] Quantised General Relativity

[0237] The classical general relativistic formula, as given by Einstein is:

$$R_{\mu\nu}-1/2g_{\mu\nu}R=-\kappa T_{\mu\nu}$$

[0238] Where R is effectively the curvature of space-time, $R_{\mu\nu}$ denotes the contracted Riemann tensor of curvature and $T_{\mu\nu}$ is the "energy tensor" of matter.)

[0239] If we substitute the energy tensor matrix of the electron (eq. 9)×time, for the energy tensor of matter $T_{\mu\nu}$; and the metric tensor of the space-time lattice×time for the contracted Riemann tensor we can arrive at the same solutions for general relativity.

[0240] Furthermore, in his published paper on General Relativity, Einstein. defined the constant κ as:

$$\kappa=8\pi G/c^2$$

[0241] Therefore Einstein's equation should be written as

$$R_{\mu\nu} - 1/2g_{\mu\nu}R = \frac{8\pi G}{c^2}\cdot T_{\mu\nu} \tag{43}$$

[0242] Einstein himself was apparently not happy about the right hand component of the equation. However, we find that this part of the equation can now be explained and quantised by substituting the gravitational constant, $G=9\pi r_q^2/\phi m_q$, (eq. 42a),

[0243] Giving:

$$R_{\mu\nu}-1/2g_{\mu\nu}R=-\frac{8\pi^2 9r_q^2}{\varphi m_q c^2}\cdot T_{\mu\nu} \tag{44}$$

[0244] By substituting $m_q \cdot c^2=h$, and further substituting h=h/2π, we arrive at a quantised solution to Einstein's equations. Where A_q is the surface area of quintessence ($A_q=4\pi r_q^2$); ϕ is the graviton [ϕ=(π/c)] and h is Plancks constant. thus:

$$R_{\mu\nu}-1/2g_{\mu\nu}R=-\frac{9A_q}{\varphi\hbar}\cdot T_{\mu\nu} \tag{45}$$

[0245] The gravitational equation can now be further understood on a logical basis. The term $A_q=(4\pi r_q^2)$, where represents standard term for the surface area of a sphere of quintessence for the 9 space dimensions of the space time lattice, h is the energy content of quintessence×time and ϕ is the graviton, thus the right hand term now represents a true "metric energy tensor" of matter.

[0246] This leads directly to the standard solution to the field equations, for the general relativistic increase in radius r' of an object, where A is the surface area of a sphere of a given mass M, such that

$$r=\sqrt{(A/4\pi)}-r=GM/3c^2 \tag{34}$$

[0247] Furthermore, although equation 45, gives the same solutions as Einstein's equation, which is essentially correct, the difference is that the equation is now dependant upon Planck's constant (h), and moreover the radius of quintessence, which now defines a quantised solution to the equations.

[0248] Graviton Force Characteristics

[0249] Similar to the photon, the previously derived equation (42) for the graviton [ϕ=(π/c)] appears to also mathematically represent a helical ringlet of quintessence, but with a spin of 2. For the photon, taking the direction of motion as the x vector and its axis of spin also as the x vector, would account for the electromagnetic force and its attraction and repulsion characteristics. In the case of the gluon component ($\pi/c^{1/2}$), if the direction vector is x, then the axis of spin would be in the y vector, the same as quasi electrons, accounting for the particle binding characteristics of the gluon force. In the case of the graviton, if the direction of motion was in the x vector, the graviton spin axis would be in the z vector thus, as will be demonstrated, accounting for the gravitational force.

[0250] The spin axis of the graviton can also be derived using the known characteristics of the electron. If an electron is travelling in the x direction, then its spin axis is determined by the by the sign of the ${}_j$y vector (up or down). This view is in agreement with conventional theory, which indicates that the electron spin is similar to a rotating planet orbiting the sun, (the electron even appears to have orbital precession). As the electron passes through the space-time lattice, this spin would generate the formation of gravitons. This would occur as a result of the ejection of the excess quintessence passing through the electron. As the electron spins, the ejection of these gravitons would occur at a tangent to the electron's direction of motion. The ejection of the gravitons would occur, similarly to the ejection of energy of a pulsar or quasar, through the equivalent of the north and south poles of the electron. Thus, propelling the graviton in the direction of the electrons y vector. The ejection of the graviton would re-orientate and impart a specific angular momentum to the gravitons which would thus end up spinning on its own z axis. If for instance the graviton is released from an up spin electron the graviton will be rotating clockwise and its leading edge will displace quintessence downwards. In turn this will provide an upwards force.

[0251] This picture accounts for Fleming's left hand rule, is logical and provides an explanation for the magnetic force around a wire. According, to the left hand rule if the direction of the current is in the x vector, the magnetic field is in the z vector, and the force is upwards, in the y vector, in accordance with the above model. Therefore, this particular spin axis and the structure of the graviton results in its force characteristics. As the graviton is very small compared to the electron and both have different rather rapid spin axis it is difficult for these to bind and interact. Nevertheless, because the graviton has a spin of 2, and as it spin axis is perpendicular to its direction of motion, in the z vector, it readily displaces space-time quintessence to produce gravity. Thus because the graviton is able to displace space-time, it is capable of escaping a black hole. How else could the effects of gravity be felt beyond a black hole?

[0252] Quantum Gravity and Electromagnetism

[0253] With the above electron model of graviton production the nature of magnetism can be understood from first principles, Furthermore, the presence of a space-time lattice links relativity, and the forces of gravity with the electromagnetic and other forces of Nature. Indeed, evidence for these links may first date back to the 1820's, when Andre Ampere first defined the Amp. The force of attraction between two parallel wires 1 metre apart each carrying 1 Amp in a vacuum was defined as none other than the permeability of free space (2×10^{-7} N per metre of conductor). Thus conventionally the magnetic field strength around a long straight wire is given as:

$$B=\mu_0 I/2\pi r$$

[0254] Where I is the current and μ_0 is the permeability of free space ($4\pi\times10^{-7}$ N A^{-2})

[0255] The attraction between two wires both carrying negative charge is, however, counterintuitive as negative charges should repel. A conventional explanation overcomes this by invoking the presence of a magnetic field which is created by the current by the production of virtual photons. Thus we appear to have an explanation for the effects of magnetism which involves virtual photons, however, these photons are not observed. More accurately, according to conventional special relativity the magnetic field is none other than the electric field viewed relativistically.

[0256] A more satisfactory explanation, therefore, lies in the interaction between the electrons and the space time lattice. The moving electrons in the two wires interact with the lattice to produce gravitons; which are in phase when both streams of electrons are traveling in the same direction. The gravitonic waves interact constructively to disperse the space time lattice between the wires and induce an attractive force between the two wires, which produces in effect the permeability of free space. Thus this force results from the vibration of quintessence itself.

[0257] Conversely in two wires with current going in opposite directions the graviton waves are in anti-phase and would interact destructively between the wires. The gravitonic waves traveling radially outward from the wires would, however, disperse the lattice outside the two wires and produce apparent repulsion between the wires, which is exactly what is observed. These effects of electricity suggest that gravitons act as waves and that phase is important.

[0258] This effect is also seen with the north and south poles of ferromagnets. Nevertheless, with matter other than iron, cobalt or nickel, the graviton emission cannot be phased as the atoms are unable to align and magnets do not appear to exist with other materials.

[0259] In ordinary magnetic system the release of gravitons from the north pole would be exactly balanced by those released from the south pole of the magnet and hence there would be no net force on the magnet until an external magnet or electrical current were applied.

[0260] Overall the magnitude of the forces in electrical systems where electrical conduction occurs are well defined by the permeability and permittivity of free space μ_0, and ϵ_0. Where v is the constant velocity of the charge and ϵ is the electric field produced by the charge.

$$B=[\mu_0\epsilon_0]v\cdot\epsilon$$

[0261] These observations suggest that the forces of electricity which produce magnetism are indeed related to the permittivity and permeability of free space and that these quantities are exerted by an apparent vacuum. Thus the effects of magnetism could be explained by none other than the phased effects of gravitational waves on the space time lattice.

[0262] Electromagnetism is of further interest to quantum gravity, particularly if we combine the standard equations, $B=\mu_0 I/2\pi r$ and $B=[\mu_0\epsilon_0]v\cdot\epsilon$, substituting for B we have:

$$2\pi r=I/\epsilon_0 v\epsilon \qquad (46)$$

[0263] Thus $2\pi r$ is proportional to the inverse of ϵ_0. Thus as space time is dispersed by gravitons the permittivity field will increase in the same way capacitance increases with separation of plates. Because of the inverse relationship between ϵ_0 and $2\pi r$, as ϵ_0 increases the circumference of a circle and the apparent ratio of π is to r, will appear to diminish in accordance with general relativity. This not an actual diminution in the circumference of a circle but the effective reduction of the resistance to motion in a circular path in this field.

[0264] Incidentally, the above observations, also lead us directly to Schrödinger's formula for the average equilibrium distance (r) between an electron with charge (e) in orbit around a proton, which is conventionally given by:

$$r=n^2 4\pi h^2\epsilon_0/me^2$$

[0265] Where ϵ_0 is again the permittivity of free space, m is the mass of the electron and n is an orbital integer, h is Planck's constant and e is the charge of the electron. Furthermore if $e=[\epsilon_0/3(4/3\pi c^3)]^{1/2}$ (eq. 3); then the equation at n=1, for the electron orbital radius elegantly simplifies to:

$$r=4h^2c^3/m$$

[0266] Hence the orbital radius of the electron is related to spin of the electron (h) and its mass (m).

[0267] Quantum Gravity and the Charge of the Electron

[0268] The equation for the charge of the electron (eq. 1) contains the term so (permittivity of free space) which according to these observations should vary in a gravitational field.

$$e=[\epsilon_0/3(4/3\pi c^3)]^{1/2} \qquad (6a)$$

[0269] If we combine the standard equations, $B=\mu_0 I/2\pi r$ and $B=[\mu_0\epsilon_0]v\cdot\epsilon$, substituting for B we have:

$$2\pi r=I/\epsilon_0 v\epsilon \qquad (46)$$

[0270] Thus $2\pi r$ is proportional to the inverse of ϵ_0. Thus as space time is dispersed by gravitons the permittivity field will increase in the same way capacitance increases with separation of plates. Because of the inverse relationship between ϵ_0 and $2\pi r$, as ϵ_0 increases the circumference of a circle and the apparent ratio of π to r, will appear to diminish in accordance with general relativity.

[0271] Thus ϵ_0 rises when space-time is dispersed by the gravitons that produce the gravitational field, This occurs in a similar way to the process by which capacitance increases with separation of plates in a capacitor.

[0272] Nevertheless, as c is a constant and as $c=[\mu_0\epsilon_0]^{-1/2}$, then if ϵ_0 rises then μ_0 falls. This is entirely consistent as μ_0, which represents the force that quintessence exerts, would be reduced if the quintessence space time lattice is dispersed.

[0273] Furthermore, as $\mu_0=4\pi\times10^{-7}$ N A^{-2}; then as μ_0 falls, then the apparent ration π to r, also falls in a gravitational field. This is largely the same as stating, as does general relativity, that the apparent radius r', rises in a gravitational field. So this view is consistent with general relativity.

[0274] Nevertheless, to derive an exact value for the charge of the electron we must account for gravity in the above equation. We will take the specific example of the Earth's gravitational field in order to obtain the exact value for the electron. If in accordance with standard general relativity, the apparent increase in radius r' is:

$$r'=GM/3c^2 \qquad (34)$$

[0275] Then given that the mass of the Earth is 5.9745×10^{24} kg; then

$$r'=1.47864\times10^{-3}\text{ m}$$

thus

$$2\pi r'=9.29057\times10^{-3}$$

[0276] Which is the incremental factor by which ϵ_0 must increase in Earth's gravitational field. So to correct ϵ_0 to account for gravity, ϵ_0 must be divided by the incremental factor, $2\pi r'$. Similarly as effectively π decreases in a gravitational field, to correct π to account for gravity it must be multiplied by this incremental factor. So the equation for an electron in a zero gravitational field is:

$$e=[\epsilon_0/3(4/3\pi c^3)]^{1/2}\div(1+2\pi r')=1.6022\times10^{-19}\ \text{C} \qquad (6b)$$

[0277] This now gives the charge of the electron as measured in a zero gravitational field as 1.6022×10^{-19} C, which is the same as that measured on Earth. Notably these observations appear to suggest that the charge of the electron is the same irrespective of the gravitational field.

[0278] Virtually unlimited degrees of accuracy for the charge of the electron and for the fine structure constant (α), may be achieved by taking into account 2nd and nth order gravitometric effects. Thus if we take into account the effect of gravity upon the radius of the Earth it is also important to take into account an effect upon the instruments with which we measure quantities, this would be a second order gravitometric effect. Thus taking into account 2nd order effects (r''), we have a very small, but nevertheless relevant change, such that: $r''=r'(1+2r')$. Thus $2r''=9.3180486\times10^{-3}$, and thus:

$$e=[\epsilon_0/3(4/3\pi c^3)]^{1/2}\div(1+2\pi r'')=1.6021765\times10^{-19}\ \text{C} \qquad (6c)$$

[0279] This agrees exactly to the nearest 7 decimal places with the maximum accuracy of the experimental value for the charge of the electron. Furthermore by taking into account the nth order gravitometric effect, it is theoretically possible to predict accuracy for the charge of the electron to 3n decimal places. This mathematically accuracy confirms the structure of the electron from first principles and indeed the theoretical effects of gravity on the permittivity of free space (ϵ_0).

[0280] This returns us directly to the fine structure constant for the electron which is conventionally given by: $\alpha=e^2/hc\cdot4\pi\epsilon_0$. If $\alpha=e^2=\epsilon_0/3(4/3\pi c^3)$, accordingly the quintessential equation for α is structurally given by: $2\pi/\alpha=m^q[3\Theta]^2$ (where $\Theta=4/3\ \pi c^3$; see The Structure of the Electron and Matter), we must now take into account the effects of gravity, as above, thus:

$$2\pi\alpha/m_q[3\Theta]^2\div(1\_\_2\pi r'')^2=0.007297353$$

[0281] Where the gravitational term for the increase in radius r'' allows the mathematical derivation of $\alpha=0.007297353$, and the above equation is in agreement with the conventional experimental value for $\alpha=0.007297353$ to the nearest 9 decimal places.

[0282] Hence the term $(1\_\_2\pi r'')^2$ is in accordance with these observations for the effect of gravity on electromagnetic forces. To a maximum accuracy governed by current knowledge of the mass of the Earth and the Gravitational constant and thus the term for the gravitational increase in radius r'. These observations can also be used to accurately predict the magnetic moment of the electron

[0283] Thus the presence of the fine structure constant can now be further understood, by deriving the constant from first principles; specifically from the actual dimensional conformation for the charge of the electron: $e=[\epsilon^0/3(4/3\pi c^3)]^{1/2}$ (eq. 6).

[0284] Overall the fine structure constant α (allowing for the term r' which is the general relativistic increase in the radius of the Earth due to gravitation) is given by none other than the formula for the mass of quintessence and from the structure of the electron, which can now be derived from first principles to seven decimal places or more.

[0285] Quantum Gravity and the Electron Magnetic Moment

[0286] The theoretical origin and nature of magnetism remains obscure in current electromagnetic theory. An explanation suggests these magnetic effects are produced by photons, although no photons have ever been observed. To get round this difficulty it is postulated by physics that magnetism results from "virtual" photons. However, Maxwell's equation for electromagnetism states that the photon has no net magnetic effect.

$$\delta B_x/\delta B_y/\delta y+\delta B_z/\delta z=0$$

[0287] Thus magnetism could not, by the above standard equation, be derived from a photon real or virtual.

[0288] In addition observational data suggests that black holes have powerful magnetic fields and as in theory photons are unable to escape from black holes (except for small quantities in the form of Hawking radiation), it would be difficult to explain these magnetic fields on the basis of photon emission.

[0289] Einstein postulated that magnetism was merely due to special relativity .sup.(ref 17). The postulate for the nature of magnetism in these current observations, states that the magnetic force results from relativity due to none other than the phased emission of gravitons (why postulate two invisible forces, magnetism and gravity, when one, the graviton, will do). This view as previously discussed (Quantum Gravity and Electromagnetism) is entirely compatible with standard relativity$^{(\text{ref }19)}$. Thus with the graviton origin of magnetism, the equation for the magnetic moment of the electron should have an expression in terms of quintessence and in turn the gravitational force and in particular the graviton.

[0290] The standard term for the magnetic moment of the Bohr Magneton (SIB) is:

$$\mu B=eh/4\pi m_e$$

[0291] In standard quantum mechanics the Bohr Magneton, μB, however, needs to be corrected to agree with experiment. The "correction factor" is termed "ϵ"; where $\epsilon=(\alpha/2\pi)-0.328\alpha^2/\pi^2=0.001159641$. Thus theory reveals μ_e, the magnetic moment of the electron where:

$$\mu_e=(eh/4\pi m_e)[1+(\alpha/2\pi)-0.328\alpha^2/\pi^2]$$

[0292] The conventional derivation of the term ϵ above, is given from the fine structure constant, $(\alpha/2\pi)$ which is theoretically consistent. However, a rather arbitrary mathematical correction term; $0.328\alpha^2/\pi^2$ needs to be used in this standard equation. This appears ad hoc and needless to say, more accurate measurements show, the electron magnetic moment to the Bohr magneton ratio, $1+\epsilon=1.001159652$, which suggests the correction factor is indeed incorrect. Nevertheless, this correction factor is essential for "renormalisation" and thus for quantum mechanics to work.

[0293] Quantum gravity readily explains the discrepancy between the theoretical Bohr Magneton (μB) and the actual measured magnetic moment of the electron (μ_e). In accordance with the above chapter (Quantum Gravity and the Charge of the Electron)

[0294] Thus the significant mathematical discrepancies can be removed by accounting for the effects of quantum gravity.

[0295] Thus taking the charge of the electron (e), using the equation for the Bohr magneton and the effects of quantum gravity such that gravitational change in radius is r". The magnetic moment of the electron is given by:

$$\mu_e=(eh/4\pi m_e)(1+[\alpha/2\pi\div(1+r'')])$$

[0296] This gives an electron magnetic moment to Bohr magneton ratio of 1.00115968. Thus the mathematical term for the magnetic moment of the electron is given, avoiding the arbitrary and dubious term $0.328\alpha^2/\pi^2$ used in the standard equation, simply by accounting for quantum gravity.

[0297] It is now possible to unite the equations for gravity and magnetism by substituting the fundamental key equations of quantum gravity. Thus if: $h=3m_qc^2$ (eq. 1b) and $m_e=m_qn_q$ (eq. 2). Then we can express the magnetic moment of any particle with the charge of the electron, including the proton, in terms of the number of quintessences (n_q) in that particle.

$$\mu B=ec^2/(4/3\pi n_q); \tag{47}$$

[0298] Given that the postulated structure of the graviton is: ($\phi=\pi/c$) (eq. 42), then substituting we have

$$\mu B=3ec/4\phi n_q \tag{48}$$

[0299] Showing that the equations for the magnetic moment are compatible with the gravitational equations given earlier. Principally, the quintessential equations now allow the determination of the magnetic moment of any charged object from the equation for the graviton and directly from the number of quintessences it contains. In conventional physics the magnetic moment of the electron requires a correction factor, $(1+(\alpha/2\pi c)-0.328\alpha^2/\pi^2)$, to derive the correct experimental value. These observations herein, indicate that the correction factor is more logically (1+r"), where r" is the general relativistic increase in radius around a gravitational body. This suggests that magnetism is not only affected by gravity, but can, as shown as above, be derived using the quantum gravitational equations.

[0300] Quantum Gravity and Special Relativity

[0301] Ordinary matter passing through the lattice would produce gravitons which would interact with space-time as described by general relativity. The quantity of gravitons would be determined by the apparent mass and in turn these would apparently curve space time. The geometry of this "curvature" is elegantly described by general relativity using Riemann geometry, specifically using metric tensors. Intriguingly the metric tensor is not a single number, but at each point in space time it is required to consist of a collection of ten numbers, Consequently, ten dimensional space-time hypotheses, such as this or superstring theory, may automatically yield general relativity

[0302] General relativity is indeed very elegant, nevertheless there was a logical step yet to answer. That is, how do gravitons shape space time? This can now be readily answered by considering the interaction of a three dimensional space time lattice with gravitons themselves to produce the effects of gravity. The effects of gravity are as such to compel a body in motion towards the gravitational object and to a much smaller extent visa versa. This effect can only be produced If gravitons repel quintessence (the constituents of the 3D lattice). Indeed, it has been stated that in order to explain cosmic inflation and the "flatness" of the Universe that quintessence must shun (or be shunned by) matter.

[0303] In descriptive terms a body close to a large mass will have a tendency to move toward it because the three dimensional lattice would be less dense as it approached the surface of the large mass. Overall there would be less resistance to motion in the direction of the large mass, and the motion in this direction would be facilitated by the vibration of quintessence.

[0304] In general relativity the principle governing motion is the geodesic of least distance, this can be re-expressed using similar equations using least action. Furthermore, the concept of motion due to the vibrations of quintessence is more logically and experimentally compelling.

[0305] These observations can now be used to link general and special relativity. Thus as we approach the speed of light, the mass of an object travelling through the space-time lattice would approach infinity, directly because the number of quintessences passing through a body would increase with increasing velocity, hence the equation:

$$m'=m_0/(1-v^2/c^2)^{1/2} \tag{50}$$

or

$$m'=m_0/(1-v^{2\,[\mu}{}_0\epsilon_0])^{1/2} \tag{50a}$$

[0306] In turn this would generate increasing gravitons and accordingly this would explain the observed effects of special relativity. Time itself is due to passage through the space-time lattice, and where the space-time lattice is dispersed by gravitons, time and length are reduced with increasing velocity and hence increasing space-time lattice dispersion, similar to the way in which gravity alters space-time

[0307] As a result:

$$t'=t(1-v^2/c^2)^{1/2},\ l'=l(1-v^2/c^2)^{1/2}$$

[0308] Thus resulting in the effects of special relativity.

[0309] Quintessence and Black Holes

[0310] To address the relationship of the space-time lattice to gravity directly, it is important to discuss the concept of quintessence with regard to general relativistic equations. The standard general relativistic equation for the apparent increase in radius (r) due to the curvature of space time around a gravitational object, which has also been previously derived from first principles (eq. 36), is:

$$r'=GM/3c^2 \tag{34}$$

[0311] This can also thus be written as:

$$3r'=GM[\mu_0\epsilon_0] \tag{51}$$

[0312] This standard equation, is in keeping with the above observations. Specifically, as the mass increases, ϵ_0 increases, in turn the radius will appear to increase (relative to π).

[0313] The above observations now allow us to examine the effects with regard to the interior of black holes themselves. The event horizon would represent a critical density for quintessence, in which light could not escape. The Schwarzschild radius would now be given by:

$$R_s=2GM[\mu_0\epsilon_0]$$

[0314] The event horizon will occur at the point at which there is less resistance to circular motion than motion in a straight or partially curved line. Given that π is proportional to $1/\epsilon_0$. The event horizon should occur when the permittivity has increased by a factor of π.

[0315] Effectively because the permittivity of free space rises, π decreases. This is entirely in keeping with general relativity which predicts the effective change in the ratio of the radius to the circumference as given by the conventional equation, where r', is again the apparent change in radius.

$$r=GM/3c^2$$

[0316] Hence π will effectively decrease as we approach the event horizon of a black hole, When π decreases to 1, the circular circumference is equal to the diameter and moreover, inside this limit it is shorter for light to travel in a circle. Thus light cannot escape the event horizon.

[0317] This can give us great insights into the workings of space-time, for flat Euclidean space the standard equation is:

$$e^{i\pi}=-1$$

[0318] In accordance with general relativity, the ratio of the radius to the circumference changes in a gravitational field, and effectively π=1, at the event horizon, thus the boundary condition for the shape of space-time at the event horizon now has the direct equation:

$$e^{f}$$

[0319] Within a black hole as the permittivity of space increases by a factor of 2π an object within it will complete two rotations rather than travel in a straight line. In effect exceeding the speed of light by 2π. Hence, the condition for space-time is represented by the equation:

$$e^{i/2}$$

[0320] Thus an increase in the permittivity of free space by a minimum factor of π, to produce a black hole is estimated to result from an increase in mass by a factor of approx. 10^6 (the ratio of the mass of the earth and that of a putative black hole).

[0321] Continuing with the subject of a black hole, according to the model inside the black hole, the gravitons produced by the matter present would be in equilibrium with the density of the space-time lattice. Increasing the rate of rotation of the matter in the black hole for instance would thus increase the production of gravitons and its effective mass and increase the radius of the event horizon. A density gradient of the space-time lattice would continue to exist within the black hole. Progressively closer to the center of a black hole matter itself would be increasingly compressed and the spherical structure of the quasi electron would be predicted to collapse. This collapse would result in the formation of an exotic form of matter in the form of pure quintessence in a black hole.

[0322] This pure quintessence would produce the singularity at the centre of the black hole. The larger the black hole in terms of mass the more pure quintessence would exist at its core.

[0323] Quintessence and the Big Bang

[0324] Quintessence theory not only predicts the occurrence of the Big Bang, but allows a prediction for the value of the entire mass of the Universe, from first principles.

[0325] In accordance with quintessence theory the big bang resulted from the explosion of an immense black hole singularity, which was constituted from pure quintessence.

[0326] On the basis of quintessence, there will be a critical mass for Big Bang event; thus if entire space-time between quintessence is compacted so that no further quintessence can be accommodated, the addition of further quintessence would destabilize the immense black hole, resulting in the Big Bang.

[0327] It is possible to predict this critical mass, using the radius of quintessence as a benchmark. Given the nine spatial parameters present in the metric tensor, used in general relativity we find that the actual formula for the radius of quintessence; r_q^2, is mathematically in agreement with general relativistic theory when:

$$9r_q^2=Gh/C^3 \tag{33}$$

[0328] This again supports the 9 dimensional view of space (so crucial in superstring theory). Moreover, the size of the vibrations of quintessence can thus be calculated as:

$$r_q=1.35\times10^{-35}\text{ m} \tag{33a}$$

[0329] The volume of each quintessence is thus:

$$4/3\pi r_q^3=1.0306\times10^{-104}\text{ m}^3 \tag{33b}$$

[0330] So to be accommodated within unit volume of space time, with no intervening apparent space time, (given that each of 9 overlapping quintessences are required) would require approx.

$$9\times10^{104}\text{ quintessences}$$

[0331] As the mass of quintessence is $m^q=h/c^2=7.373\times10^{-51}$ kg sec (eq. 1). Then the mass of the Universe, to two decimal places, is:

$$1.18\times10^{53}\text{ kg} \tag{33c}$$

[0332] This is in close agreement with a recent estimate of the mass of the Universe from COBE and other satellite data, which estimates the mass to be 100 trillion trillion trillion trillion tonnes (10^{53} kg)

[0333] Moreover, the early formation of the galaxies can be readily explained, it is likely that in such a big bang some very small black holes might have prevailed and that these formed the seeds of the galaxies we see today.

[0334] The event horizon, calculated from the Schwartzschild radius, of such an immense black hole is about 10^{26} m, which would have allowed Guth's inflationary component to the early expansion of the Universe.

[0335] In addition, inflation may result directly from the observation that once electrons have formed from the primordial soup of quintessence, they emit gravitons which in turn repel space time, which might also result in another cosmic inflationary cycle.

[0336] Most importantly quintessence theory explains the Big Bang from first principles and is capable of accurately predicting the mass of the Universe.

[0337] The Nature of Energy

[0338] These observations allow a fundamental understanding of energy. The quantum physical, minimum component of energy is Planck's constant; h. To define the minimal component of mass, using the standard energy equivalence formula; $E=mc^2$, such a minimal mass (m_q)

would be required to have the value equivalent to; $m_q=h/c^2$ (1). The total mass of a system (m) would then be; $m=m_q n_q$, where (n_q) is the number of these minimal units. Thence, the total energy of a system can be derived from the minimal energy; h, multiplied by the number of these energy units (n_q). Thus as, $E=mc^2$, then also $E=m_q n_q c^2$ and substituting $m_q=h/c^2$, the energy equivalence formula has the more logical formulation;

$$E=hn_q \tag{1a}$$

[0339] Thus the energy of a system is equivalent to the minimal energy unit; h, multiplied by the number of those minimal energy units (n_q)

[0340] This leads directly to a deeper understanding of wave particle duality and the wave nature of matter.

[0341] This is encapsulated by the quintessential energy formulae

[0342] As conventionally $\beta \cdot E/c=p$, then

$$\lambda=h/p=hc/\beta E \tag{2}$$

and

$$E=hn_q \tag{1a}$$

then

$$\lambda=c/\beta n_q \tag{2b}$$

[0343] Importantly, as indicated by equation (2b), energy having no quintessence; would have a wavelength of infinity. Specifically pure energy containing no quintessences, would have a lambda of infinity. According to quantum mechanics an infinite wavelength would result in the probability of that energy being anywhere. As energy itself has no electrical charge it would not be impeded by the permittivity and permeability of the three dimensional space-time lattice. Moreover, energy would not be detectable in three dimensional space-time, unless it interacted with matter, as in the EPR experiments. Indeed, energy is not observed when not bound to any form of mass or particle.

[0344] Thus equation 2b, takes us to our original assertion regarding the existence of pure energy.

[0345] Energy is not Bound by the Space-Time Lattice

[0346] Thus, as the EPR experiments suggest the existence of energy separate from matter and thus separate from the three dimensional space-time lattice, it is interesting to find that experiment suggests the existence of free energy in a continuum separate from space time and matter to produce the effects of quantum teleportation.

[0347] This is not, however, teleportation across an additional dimension, this is a term to describe in partially familiar terms the dissociation of energy from the three dimensional space-time lattice. As time is inextricably linked to each dimension of space, the effects of energy would be inextricably linked to the events, such as the creation of virtual particles, we see interacting within space-time. It is unlikely that observers have any direct day to day experience to explain quantum events. Nevertheless, quintessence theory may have given us a window into the hitherto hidden workings of the Universe. Thereby, the mystery of the uniformity of the Universe, across distances which the speed of light could not apparently traverse, is readily explained by the fact that the free energy contained in the Universe is not bound by the space-time lattice.

[0348] In the case of light, due to the exceedingly small masses involved, there would be relatively easy exchange of matter with free energy within a photon. This would make the photon the ideal experimental tool to look for energy which is not bound by matter and in turn energy which is not bound in space-time. Indeed, very recently Furusawa et al. have reported to have observed the transference of energy as photons from A to B, without those photons traversing space-time. This finding which has been supported using other experimental techniques, is very important as it suggests the existence of such free energy.

[0349] Overall, quintessence theory gives an a priori explanation for the concept of mass, the elementary particles, the forces of nature and quantum effects. It can equally be used logically to explain the inner physics of a black hole, the missing mass in the Galaxy, the expansion of the Universe, Guth's inflationary theory and predicts the Big Bang, from first principles.

[0350] Part IV: Applied Theory with the Intent to Create Closed Timelike Curves

[0351] Electron Bombardment of the Photosphere to Induce Gravitational Shift

[0352] Leveraging the above relationship between mass and quintessence we derive that if an electromagnetic radiation with velocity v strikes the event horizon singularity of rest inertial mass mi, and U is the electromagnetic energy absorbed by the singularity, then, according to Maxwell's prediction, a momentum q=U/v is transferred to it. Mass shift $d \cdot m_b$, dependent on the external electromagnetic energy, equals the inertial mass shift dependent on the increment of energy in the particle. Since in this case the inertial mass shift does not depend on velocity V, i.e., it is related only to the momentum q absorbed, it can be obtained by making p=0 in variation $\Delta H=H'-H=c[q^2+(m_i c)^2]^{1/2}-(m_i c)^2$ from the particles inertial Hamiltonian. Consequently, the expression of d_{m_p}, is written as:

$$d_{m_p}=\Delta H/c^2=m_i\sqrt{1+U/m_i c^2\left[\varepsilon_r u_{r/2}\left\{\sqrt{1+d/w\varepsilon^2+1}\right\}^2=1\right.}$$

[0353] Comparing now the expression of m_i and m_g we have $m_g=m_i-2dm_b$. By replacing m_b in this equation, given by equation above, we obtain the expression of the correlation between gravitational mass and inertial mass, i.e.,

$$m_g=m_t-2\sqrt{1+U/m_t c^2\left[\sqrt{\varepsilon_r u_{r/2}\{[d/we]^2+1\}^2-1}\right.}\cdot m_t$$

[0354] We see that only in the absence of electromagnetic radiation on the event horizon (U=0) is the gravitational mass equivalent to the inertial mass. Note that the electromagnetic characteristics, e, m and s do not refer to the singularity itself, but to the outside medium around the singularity (photosphere) in which the incident radiation is propagating.

[0355] Stable CTC Solution From Modified M-Theory

[0356] Our innovation is a method of creating an event where a dual membrane or dual boundary condition exists. We do this using generalization from a Misner space which has been modified if one analytically continues the maximal extended Misner Metric so that $ds^2=-du^2+dw^2+(dx^2)^2+(dx^3)^2$ to the Euclidean section so that u=iota zeta we obtain a Misner instanton on the section where w and zeta are both real. The Euclidean time, t, and the closed spacelike coordinate are both periodic, the later having a period of $2\Pi t^2$. Going back to the Lorentzian sector we find that the period of the closed coordinate becomes linearly dependent on the physical time. Using automorphic fields in the Hadamard function one can obtain a quantized condition for time. This gives us a figure on the order of the Plank time. This confines such a stable wormhole condition to the general area of the Plank scale in its modified form which is that area defined by the Membrane itself. As such, these Plank scale wormholes are the true source of the true virtual aspects of the vacuum and quintessence. The effects of the dual singularity system can be viewed as an overlap zone of two distinct space-times which have boundary conditions on both sides. As an object accelerates towards C it is this same boundary or horizon that object encounters when the Time defined horizon solution for the universe is imposed. At this point drawing upon Van Den Broeck's alterations for this space-time geometry to create a single closed Friedman-Robertson-Walker spacetime the space-time geometry can be represented by this equation $ds^2=dct^2-B^2[(dx-\beta fdct)^2]+dy^2+dz^2$ B can be any function that is large near the displacement device. We then consider this transformation as extended to four dimensional space-time with arbitrarily time dependent acceleration. We also present the device frame energy density T00 from a four dimensional calculation and note that the 4d classical calculation is everywhere finite.

[0357] Consider an Alcubierre interval given according to a remote frame's cylindrical coordinates by:

$$ds^2=(1-\beta^2f^2)dct^2+2bfdctdz-dz^2-dr^2-r^2df^2$$

where f is a function that is 1 at the location of the device and zero far from it.

[0358] Starting out with the first transformation z'=z−òct beta dct. Where b is first expressed here as a function of time ct. With some algebra for simplification this results in

$$ds^2=[1-\beta^2(1-f)^2]dct^2-2b(1-f)dctdz'-dz^2-dr^2-r^2df^2$$

Let g=1−f and this becomes

$$ds^2=[1-\beta^2g^2]dct^2-2bgdctdz'-dz'^2-dr^2-r^2df^2$$

[0359] Notice that this returned the original intervals form with a reversal on the sign of b and a reversal of the boundary conditions for g. Now we notice that at r=0, this interval becomes the interval for special relativity transformed to cylindrical coordinates. Thus, we have found a transformation to a frame based local to the device. One can also verify that in these coordinates the relevant affine connections vanish at r=0. a further proposed modification to this field we will reintroduce a time dilation term into the devices frame's interval. Only we will use different boundary conditions for it. We will keep A=1 both at the location of the device, and far from it, but allow it to become large in the warped region. This is achieved by the simplest means possible in the proposed field generation method. Since rotating kerr singularity under bombardment would produce an equal negative energy region. With the effect focused outward away from the device slightly by the relative alignment of the kerr singularity the actual inward going portion of such fields would overlap and cancel their effect out in the region of the device. This yields a space normal time region, which is again restored at the fringes of the outward going field. From the standpoint of a geometric picture of space-time around the device and extending outwards one has actually created a dual event horizon situation as far as time goes. The inner one is the shell of the canceled out field inside of which normal time flow is restored. The outer one is formed at the boundary where normal time resumes and within which we have a negative energy field.

SUMMARY OF THE INVENTION

[0360] The present invention is A method for the generation of a pseudo 2+1 dimensional anti-de Sitter space (DeDeo & Gott 2002) using two Kerr type positively charged rotating dilation singularities where one singularity is maintained as a axis of rotation or "reference" singularity, and the other "target" singularity is subjected to a differential electron flow so as to simultaneously pass above the photosphere of said singularity in its direction of rotation—prograde orbit—and contrary to its direction of rotation—retrograde orbit—to release a directed flow of gravitons in a sinusoidal oscillation simulating a rotational effect of the "target" singularity around the axis of rotation provided by the "reference" singularity, resulting in the creation of timelike curves in a compact time-oriented manifold permitting topology change from one spacelike boundary to the other in accordance with Geroch's theorem (Geroch 1967) which results in a method for the formation of G odel-type geodesically complete spacetime envelopes complete with closed timelike curves.

BRIEF DESCRIPTION OF THE DRAWINGS

[0361] **FIG. 1** is a schematic representation of the mechanism employed to house the components necessary to generate a 2+1 dimensional anti-de Sitter space, resulting in the creation of timelike curves in a compact time-oriented manifold

[0362] **FIG. 2** is a schematic representation of the G odel-type geodesically complete spacetime envelope created by the mechanism complete with closed timelike curves

DETAILED DESCRIPTION OF THE INVENTION

[0363] Principles of Gravity Distortion Time Displacement Systems

[0364] The theoretical understanding of quantum gravity allows the design of time displacement systems from first principles. It is unlikely that gravitons or Kerr singularities can be controlled in a precise way using current technology. Nevertheless, an understanding of three dimensional space-time and matter, does allow the design of elementary displacement systems. That is, systems whose displacement rely on direct warping space-time as opposed to the ejection of material to provide thrust resulting in time dilatational effects.

[0365] The background for these systems are already partially understood and quintessence theory allows their further development. For this invention, the formation of black holes in the laboratory represents a crucial step in understanding the mechanisms that underlay gravitational physics and in turn the warping of space-time. The existence of black holes permits the localized application of the Axial torsion Spin-Rotation Coupling Effect (Zhang & Beesham 2002) resulting in a Rotating Frame with Relativistic Factor (Zhang 2003) which can be used in the creation of a Alcubierre space time bubble under the Van Den Broeck modification of the Alcubierre geometry (Van Den Broeck 1999) resulting in a method for the generation of a pseudo 2+1 dimensional anti-de Sitter space (DeDeo & Gott 2002) using two Kerr type positively charged rotating dilation singularities where one singularity is maintained as a axis of rotation or "reference" singularity, and the other "target" singularity is subjected to a differential electron flow so as to simultaneously pass above the photosphere of said singularity in its direction of rotation and contrary to its direction of rotation to release a directed flow of gravitons in a sinusoidal oscillation simulating a rotational effect of the "target" singularity around the axis of rotation provided by the "reference" singularity. In this instance the space-time lattice would be repelled by gravitons in such a way as to disperse space-time quintessence in a circular fashion around each of the singularities, producing multiple event horizons around the simulated axis of rotation provided by the reference singularity.

[0366] The release of gravitons from the target singularity is controlled by differentially governing the electron flow across the photosphere with the use of powerful electric currents. In turn the differential direction of flow across the photosphere of gravitons would determine the direction of motion through the space time lattice and the resulting time displacement from one spacelike boundary to the other in accordance with Geroch's theorem (Geroch 1967) when implementing this approach it is important to remember that the black hole is not excited by the smashing of the clump as it "hits" the horizon. The hole is rather excited when the metric perturbation associated with the clump is "felt" by the background metric. The excitation event therefore constitutes a smooth process whereby in-fall of a clump from .rmb and through r+ serves as a source in the Teukolsky (1973) equation for small perturbations to the Kerr geometry (with appropriate boundary conditions at r+ and r∞). This is an important distinction with a great deal of relevance to the practical engineering of the displacement unit since we need to gauge the "driving" of QNR modes in terms of an e_ective coupling from clump in-fall.

[0367] What results is a method for resonant driving of the quasi-normal ringing (QNR) wave modes of the Kerr geometry of the target singularity. The micro black hole hyper-accreting at rates ÿ M. 1 M□sec. 1 from a neutrino cooled disk is pushed through to oscillate near resonance of its (l,m=2, 2) quadrupole QNR frequency due to the in-fall of compact mass over-densities from the cusp in e_ective potential on a dynamical time scale. This mode is induced via induced magneto-rotationally induced fluid dynamics in the ultra-relativistic region of the flow bounded from below by the marginally bound orbit radius: rmb If the QNR modes are fed resonantly for a few seconds of hyper-accretion, the enhanced amplitude of the oscillations yields a very high rate of energy deposition into gravitational waves. Indeed, the integrated energy deposition is large enough to "evaporate" the equivalent of a factor of a few times the total rest mass-energy of a single clump into gravitational waves, which in turn interact with the reference singularity

[0368] Application of the method described in the previous section results in translation outside of the cosmological horizon, where F(R)<0. The topology of the resulting geodesic, for large constant R, is mathematically equivalent to a Euclidean cylinder of the condition R×Sn where T is the coordinate along the cylinder. I± are located outside the future/past cosmological horizons, where R is timelike and T is spacelike. In the case of a rotating Kerr black hole, there are two circular photon orbits that can exist in the equatorial plane and be exploited to create a tipler sinusoid. One is a prograde orbit moving in the same direction as the black hole's rotation, while the other is a retrograde orbit moving against the black hole's rotation. Their radii are respectively given by

$$r1=2M(1+\mathrm{Cos}(2/3\ \arccos(-|\alpha|/M)))$$

$$r2=2M(1+\mathrm{Cos}(2/3\ \arccos(|\alpha|/M)))$$

where a is the angular momentum per unit mass of the black hole. The orbits fall in the range M greater or equal to r1 greater or equal to 3M greater or equal to r2 greater or equal to 4M The fact that a prograde photon or in or case cooper pair with Bose characteristics orbits the black hole at a smaller radius than a retrograde one can be attributed to the well-known Lense-Thirring effect, i.e., the dragging of inertial frames due to the black hole's rotation which we control and influence via electromagnetic induced load coupling with the open magnetic field lines threading the BH horizon. This dragging would cause charged cooper pairs to revolve around the black hole relative to a static observer at infinity. Thus, to such an observer, a prograde cooper pair would have to orbit at a smaller radius to compensate for the 'extra' angular momentum acquired, while a retrograde one would have to orbit at a larger radius to compensate for the 'lost' angular momentum. Indeed, in the limit of zero rotation, these two orbits coincide at r D 3M, giving the single circular orbit of the Schwarzschild black hole. Now, recall that orbits around the Schwarzschild black hole are necessarily confined to a plane passing through its center, because of the spherical symmetry of the space-time. However, the Kerr black hole space-time has only an axial symmetry (in addition to being stationary), and this raises the possibility of non-planar orbits. One could, for example, contemplate the existence of spherical Boseon orbits—orbits with constant coordinate radii that are not necessarily confined to the equatorial plane—around the Kerr black hole. Such orbits would be a nontrivial generalization of the two circular photon orbits that lie in the equatorial plane. At first it may seem a little surprising that such spherical orbits could even exist, but there is an interesting reason as to why they are possible. Note that an object in a spherical orbit would, in addition to moving around the black hole in the azimuthal direction, be undergoing some periodic motion in the latitudinal direction. This is only possible if there is a conserved quantity associated with motion in this direction, just as angular momentum is necessarily conserved by its rotational motion in the azimuthal direction. (This result can be seen, for example, using action-angle variable) Now, because the Kerr space-time has only axial symmetry, geodesics in it should have only two constants of motion, namely energy and angular momentum. However, Carter discovered the remarkable fact that geodesics in the Kerr space-time possess a third constant of motion. It turns out that Carter's new constant governs the motion of geodesics in the latitudinal direction, although it is not related to any obvious space-time symmetry. Thus, spherical timelike orbits, which assume eigenlike properties around the Kerr black hole, are possible and when coupled with charged Bosons may be exploited to manipulate the relative event horizons of the "target" singularity. The location and the temperature of the modified event horizon depend on the time, charge and angle of incidence of the cooper pairs. The Fermionic spectrum of Dirac particles displays a spin-rotation coupling effect due to the interaction between the particles with spin-1=2 and the black holes with rotation. The effects arise from the interaction between the spin of Dirac particles and the rotation of the evaporating black holes. The feature of this spin-rotation coupling effect is its dependence on different helicity states of coupled particles with spin-½ and its irrelevance to the mass of particles.

[0369] In order to design a mechanism for time displacement exploiting the Carter asymettry cited above we utilize two positively charged top spin rotating kerr type black holes aligned on demand to create a simulated rotational effect around a central axis provided by the "reference" singularity. In the case of the Kerr blackhole (singularity), this is accomplished by an inverse Blandford-Znajek (BZ) process utilizing the magnetic flux of open field lines connecting the horizon and an induced remote load. (Ding-Xiong Wang, Kan Xiao & Wei-Hua Lei, 2001) permitting the microscopic blackhole (singularity) to be rotated along its horizontal axis in at relativistic centrifugational speeds. A differential current is then applied in such a way as to pass through the entire photosphere in the desired direction. As a result the gravity field can be manipulated by three factors that affect it in distinct ways. Adding electric charge to the singularities increases the diameter of the inner event horizons. Adding mass to the singularities increases the area of gravitational influence around the singularities. Rotating and positioning the polar axis of the singularities affects and alters the resulting gravity sinusoid

[0370] In order to create a sinusoid capable of inducing a topology change from one spacelike boundary to the other in accordance with Geroch's theorem The electric charge in the upper half of the photosphere would be maximised. The electrons will have a vector in the left to right direction as the singularity spins clockwise. If a maximised current is applied to the singularity in the same direction this will result in a increase in the velocity of the electrons relative to the centre of gravity of the singularity, due to the flow of current. In turn, according special relativity and to the space-time lattice model, this wilt result in an increase in the relativistic mass if the electrons and in turn by general relativity an increase in the release of gravitons.

[0371] Conversely in the lower half of the singularity the electrons will have a vector of motion in the right to left direction due to the spin of the singularity. This will be relativistically slowed by the differential current applied in the same direction as the current above, and hence in the opposite direction to the direction of rotation. The charge can be separately applied and adjusted to ensure that the electrons are relativistically stationary relative to the centre of gravity. In turn this will minimize the relativistic mass and result in a decrease in the release of gravitons for the lower half of the singularity.

[0372] The overall result will be a greater release of gravitons in one direction and a lesser release of gravitons in the converse direction. The effect will be enhanced by the use of a multi-phasic current simultaneously applied. This will result in the release of multi-phasic gravitons which will disperse space time in the singularity with increase in density in the converse this effect can also be produced and supplemented with the use radio frequency pulses, The radio frequency pulses must be designed to produce a change in the spin of the particle to enhance the release of gravitons in the desired direction

[0373] With the use of large currents the drift velocity of the electrons across the photosphere could be greatly increased. Within this region the electrical resistance is virtually eliminated. Thereby allowing large currents to be induced with minimum total power output.

[0374] The result is the production of cooper paired electrons of high speed and hence high relativistic mass in the desired half of the singularity, whilst producing low speed and thus low mass paired electrons at the converse of the singularity, in accordance with special relativity. The imbalance in the rotating singularity will be continuously present creating a dynamic warping of space-time. In effect, the differential current flow, will produce differential graviton production and in turn, by general relativity, the warping of space-time

[0375] As the cooper pairs cross the photosphere, accretion of the Bose particles results. Near-hole accretion across the target singularity is then motivated by magneto-rotationally induced, ultra-relativistic disk dynamics in the region of the flow bounded from below by the marginally bound geodesic radius rmb. As the particles impelled have high spin values, a largely coherent magnetic field in this region has the dynamical implication of compact mass segregation at the displacement nodes of the non-axisymmetric, MRI modes. This results in prolific gravitational wave emission coincident with the gamma-ray stage. The gravitational wave emissions are then manipulated to influence the reference singularity to produce a variable gravitational sinusoid which is then used to mathematically approximate the gravametric distortion, inducing a topology change from one spacelike boundary to the other in accordance with Geroch's theorem.

[0529] Appendix A: The Synthetic creation of micro singularities. Throughout this patent application the creation of micro singularities has been maintained. While at first glance this may seem to be a deficiency in the patent application it is in fact an engineering problem that is in the process of being solved. In the International Journal of Theoretical Physics 41 (11): 2073-2090, November 2002 L. J. Garay published "Black Holes in Bose-Einstein Condensates". In this article Garay showed that there exist both dynamically stable and unstable dilute-gas Bose-Einstein condensates that, in the hydrodynamic limit, exhibit a behavior completely analogous to that of gravitational black holes. This discovery coupled with creation of color glass condensate (CGC) an extreme form of nuclear matter in which a nucleus travels at near-light (relativistic) speed which flattens like a pancake in its direction of motion and spawns a large number of gluons hold the key to high energy singularity formation.

I claim:

1. A method for the generation of a pseudo 2+1 dimensional anti-de Sitter space comprising the steps of:

creating two Kerr type positively charged rotating dilation singularities, including the steps of

maintaining one of the singularities as a axis of rotation reference singularity,

maintaining the other of the singularities as a target singularity, and

subjecting the target singularity to a differential electron flow so as to simultaneously pass the differential electron flow above a photosphere of said target singularity in a direction of rotation thereof and contrary to the direction of rotation thereof, in order to release a directed flow of gravitons in a sinusoidal oscillation simulating a rotational effect of the target singularity around the axis of rotation provided by the reference singularity.

2. A method of generating a force around a body, comprising the steps of:

employing sinusoidal oscillations of electrical bombardment on the surface of one Kerr type reference singularity in close proximity to a second Kerr type target singularity to take advantage of the Lense-Thirring effect, wherein the electrical currents employed in the bombardment are passed simultaneously across the photosphere of said reference singularity in its direction of rotation and contrary to its direction of rotation to release a directed flow of gravitons in a sinusoidal oscillation simulating a rotational effect of the target singularity around the axis of rotation provided by the reference singularity;

creating timelike curves in a compact time-oriented manifold of Godel-type geodesically complete spacetime envelope under the Van Den Broeck modification of the Alcubierre geometry, resulting in the creation of timelike curves in a compact time-oriented manifold permitting topology change from one spacelike boundary to the other in accordance with Geroch's theorem.

(57) **ABSTRACT**

Disclosed is a power transmission system for wirelessly powering a power harvesting device. The system comprises at least one RF power transmitter. The system includes an AC power grid, or a DC grid to which the transmitter is electrically connected. Also disclosed is an adjustable RF power transmitter for powering wirelessly an RF power harvesting- device. Also disclosed is a power transmission system for wirelessly powering an RF power harvesting device. The system can include a computer with an antenna or a lighting fixture or a light or a battery charging unit or a battery. Also disclosed is an apparatus for wirelessly powering a power harvesting device. Also disclosed is a method for wirelessly powering a power harvesting device.

IMPLEMENTATION OF AN RF POWER TRANSMITTER AND NETWORK

BACKGROUND OF THE INVENTION

[0001] 1. Field of the Invention

[0002] The present invention is related to transmitting wirelessly power to a power harvesting device. More specifically, the present invention is related to implementing a power transmitter for the wireless transmission of power to a power harvesting device.

[0003] 2. Description of Related Art

[0004] As processor capabilities have expanded and power requirements have decreased there has been an ongoing explosion of devices that operate completely independent of wires or power cords. These "untethered" devices range from cell phones and wireless keyboards to building sensors and active Radio Frequency Identification (RFID) tags.

[0005] Engineers and designers of these untethered devices continue to have to deal with the limitations of portable power sources, primarily using batteries as the key design parameter. While the performance of processors and portable devices has been doubling every 18-24 months driven by Moore's law, battery technology in terms of capacity has only been growing at measly 6% per year. Even with power conscious designs and the latest in battery technology, many devices do not meet the lifetime cost and maintenance requirements for applications that require a large number of untethered devices, such as logistics and building automation. Today's devices that need two-way communication require scheduled maintenance every three to 18 months to replace or recharge the device's power source (typically a battery). One-way devices that simply broadcast their status without receiving any signals, such as automated utility meter readers, have a better battery life typically requiring replacement within 10 years. For both device types, scheduled power-source maintenance is costly and can be disruptive to the entire system that the device is intended to monitor and/or control. Unscheduled maintenance trips are even more costly and disruptive. On a macro level, the relatively high cost associated with the internal battery also reduces the practical, or economically viable, number of devices that can be deployed.

[0006] The ideal solution to the power problem for untethered devices is a device or system that can collect and harness sufficient energy from the environment. This energy can be harnessed from many different sources, such as sunlight, vibration, heat, or electro-magnetic radiation. The harnessed energy would then either directly power an untethered device or augment a power supply. However, this ideal solution may not always be practical to implement due to low energy in the environment, and site restrictions may limit the ability to use a dedicated energy supply. The proposed invention takes these factors into account and provides a solution for both the ideal situation and also for more restrictive circumstances.

BRIEF SUMMARY OF THE INVENTION

[0007] The present invention pertains to a power transmission system for wirelessly powering a power harvesting device. The system comprises at least one RF power transmitter. The system comprises an AC power grid to which the transmitter is electrically connected.

[0008] The power grid can have an outlet. The transmitter can have a cord which plugs into the outlet. The transmitter can plug directly into the outlet. The power grid can have a light. The transmitter can include an AC to DC converter that can convert the AC power obtained from the grid to a usable DC voltage or current.

[0009] The present invention pertains to a power transmission system for wirelessly powering a power harvesting device. The system comprises at least one RF power transmitter. The system comprises a DC power grid to which the transmitter is electrically connected.

[0010] The present invention pertains to an adjustable RF power transmitter for powering wirelessly an RF power harvesting device. The transmitter comprises a housing having outer dimensions no greater than 3"×3" by 8 inches. The transmitter comprises a power input. The transmitter comprises a frequency generator in communication with the power input. The transmitter comprises an amplifier in communication with the frequency generator. The transmitter comprises a controller connected with the frequency generator. The transmitter comprises an antenna connected to the amplifier.

[0011] The present invention pertains to a power transmission system for wirelessly powering an RF power harvesting device. The system comprises a computer with an antenna. The system comprises an RF transmitter in communication with the antenna. The system comprises a power supply in electrical communication with the RF transmitter and the computer.

[0012] The present invention pertains to an apparatus for wirelessly powering a power harvesting device. The apparatus comprises at least one RF power transmitter. The apparatus comprises a lighting fixture in which the transmitter is disposed and from which the transmitter receives power.

[0013] The lighting fixture can be a fluorescent lighting fixture. The lighting fixture can be an incandescent lighting fixture. The apparatus can include a light source in electrical communication with the lighting fixture.

[0014] The present invention pertains to a power transmission system for wirelessly powering a power harvesting device. The system comprises at least one RF power transmitter. The system comprises a track supplying power to which the transmitter is electrically connected.

[0015] The present invention pertains to a power transmission system for wirelessly powering a power harvesting device. The system comprises at least one RF power transmitter. The system comprises a battery charging unit to which the transmitter is electrically connected.

[0016] The present invention pertains to a power transmission system for wirelessly powering a power harvesting device. The system comprises at least one RF power transmitter. The system comprises at least one rechargeable battery to which the transmitter is electrically connected.

[0017] The present invention pertains to a method for wirelessly powering a power harvesting device. The method comprises the steps of electrically connecting at least one RF power transmitter to an AC power grid. There is the step of transmitting power with the RF power transmitter.

[0018] The present invention pertains to a method for wirelessly powering a power harvesting device. The method comprises the steps of electrically connecting at least one RF power transmitter to a DC power grid. There is the step of transmitting power with the RF power transmitter.

[0019] The present invention pertains to a method for wirelessly powering a power harvesting device. The method comprises the steps of electrically connecting a power supply with an RF transmitter and a computer. There is the step of transmitting power with the RF power transmitter.

[0020] The present invention pertains to a method for wirelessly powering a power harvesting device. The method comprises the steps of electrically connecting at least one RF power transmitter with a lighting fixture in which the transmitter is disposed and from which the transmitter receives power. There is the step of transmitting power with the RF power transmitter.

[0021] The present invention pertains to a method for wirelessly powering a power harvesting device. The method comprises the steps of electrically connecting at least one RF power transmitter to a battery charging unit. There is the step of transmitting power with the RF power transmitter.

[0022] The present invention pertains to a power transmission system for wirelessly powering a power harvesting device. The system comprises at least one RF power transmitter. The system comprises means for providing power to which the transmitter is electrically connected.

[0023] The present invention pertains to an apparatus for wirelessly powering a power harvesting device from a DC power outlet of a vehicle, as shown in FIG. **11**. The apparatus comprises an RF power transmitter. The apparatus comprises a power plug to which the transmitter is attached and electrically connected that plugs into the DC power outlet.

[0024] The present invention pertains to an apparatus for wirelessly powering a power harvesting device from an AC power grid having an AC power outlet. The apparatus comprises an RF power transmitter. The apparatus comprises a power plug to which the transmitter is electrically connected that electrically connects with the AC power outlet.

[0025] The present invention pertains to an apparatus for wirelessly powering a power harvesting device from a DC power outlet of a DC grid. The apparatus comprises an RF power transmitter. The apparatus comprises a power plug to which the transmitter is electrically connected that electrically connects with the DC power outlet.

[0026] The present invention pertains to an apparatus for wirelessly powering a power harvesting device from a computer having an antenna and a power supply. The apparatus comprises an RF power transmitter. The apparatus comprises a power plug to which the transmitter is electrically connected that electrically connects with the computer.

[0027] The present invention pertains to an apparatus for wirelessly powering a power harvesting device from a light fixture. The apparatus comprises an RF power transmitter. The apparatus comprises an electrical interface to which the transmitter is electrically connected that electrically connects with the light fixture.

[0028] The present invention pertains to an apparatus for wirelessly powering a power harvesting device from a track having at least one light. The apparatus comprises an RF power transmitter. The apparatus comprises an electrical interface to which the transmitter is electrically connected that electrically connects with the track.

[0029] The present invention pertains to an apparatus for wirelessly powering a power harvesting device from a battery charging unit. The apparatus comprises an RF power transmitter. The apparatus comprises an electrical interface to which the transmitter is electrically connected that electrically connects with the battery charging unit.

BRIEF DESCRIPTION OF THE SEVERAL VIEWS OF THE DRAWINGS

[0030] FIG. **1** is an illustration of an RF power transmitter integrated into an RF power network via direct hardwiring to an AC power grid;

[0031] FIG. **2** is an illustration of an RF power transmitter integrated into a vehicle;

[0032] FIG. **3** is an illustration of an RF power transmitter;

[0033] FIG. **4** is an illustration of an RF power transmitter integrated into an RF power network via replacing an AC outlet on an AC power grid;

[0034] FIG. **5** is an illustration of an RF power transmitter integrated into an RF power network via replacing a light source;

[0035] FIG. **6** is an illustration of an RF power transmitter integrated into an RF power network via use in combination with a light source;

[0036] FIG. **7** is an illustration of an RF power transmitter integrated into an RF power network via integration of the RF power transmitter and a light source;

[0037] FIG. **8** is an illustration of a lighting fixture containing an RF power transmitter;

[0038] FIG. **9** is an illustration of an RF power transmitter integrated into an RF power network via connection to an AC outlet through a cord;

[0039] FIG. **10** is an illustration of an RF power transmitter integrated into an RF power network via direct connection with an AC outlet;

[0040] FIG. **11** is an illustration of an RF power transmitter that plugs into a DC power outlet in a vehicle;

[0041] FIG. **12** is an illustration of an RF power transmitter and battery recharger integrated into an RF power network via direct connection with an AC outlet;

[0042] FIG. **13** is an illustration of an RF power transmitter plugged into a USB port of a laptop computer;

[0043] FIG. **14** is an illustration of an RF powered RF power transmitter used to relay power;

[0044] FIG. **15** is an illustration of RF power transmitters integrated into an RF power network connected to a track that provides AC or DC power;

[0045] FIGS. **16**_a-d_ are illustrations of various tracks useable with the network illustrated in FIG. **15**; and

[0046] FIG. **17** is an illustration of an RF power transmitter useable with a two-cable track.

DETAILED DESCRIPTION OF THE INVENTION

[0047] A complete understanding of the invention will be obtained from the following description when taken in connection with the accompanying drawing figures wherein like reference characters identify like parts throughout.

[0048] For purposes of the description hereinafter, the terms "upper", "lower", "right", "left", "vertical", "horizontal", "top", "bottom", and derivatives thereof shall relate to the invention as it is oriented in the drawing figures. However, it is to be understood that the invention may assume various alternative variations and step sequences, except where expressly specified to the contrary. It is also to be understood that the specific devices and processes illustrated in the attached drawings, and described in the following specification, are simply exemplary embodiments of the invention. Hence, specific dimensions and other physical characteristics related to the embodiments disclosed herein are not to be considered as limiting.

[0049] The present invention pertains to a power transmission system **10** for wirelessly powering a power harvesting device **12**, as shown in FIG. **1**. The system **10** comprises at least one RF power transmitter **14**. The system **10** comprises an AC power grid **16** to which the transmitter **14** is electrically connected.

[0050] The power grid can have an outlet **18**. The transmitter **14** can have a cord **20** which plugs into the outlet **18**, as shown in FIG. **9**. The transmitter **14** can plug directly into the outlet **18**, as shown in FIG. **10**. The power grid can have a light **22**, as shown in FIG. **1**. The transmitter **14** can include an AC to DC converter **28** that can convert the AC power obtained from the grid to a usable DC voltage or current. Preferably, the power grid has a light switch **24** to turn on the light **22**. The grid preferably includes in wall wiring **33**. The transmitter **14** can be integrated with the outlet **18**, as shown in FIG. **4**. The grid can have a lighting fixture **26** and the transmitter **14** contacts the fixture **26**, as shown in FIG. **5**. The grid can have a lighting fixture **26** and the light **22** and the transmitter **14** can contact the fixture, as shown in FIGS. **6** and **7**.

[0051] The grid can include a utility pole **32** to which the transmitter **14** is in contact, as shown in FIG. **2**. The grid can include a junction box **34** to which transmitter **14** is in contact, as shown in FIG. **1**.

[0052] The present invention pertains to a power transmission system **10** for wirelessly powering a power harvesting device **12**, as shown in FIG. **2**. The system **10** comprises at least one RF power transmitter **14**. The system **10** comprises a DC power grid **30** to which the transmitter **14** is electrically connected.

[0053] Preferably, the transmitter **14** is disposed in a vehicle **36**. The transmitter **14** can provide a coverage area **38** over the cabin of the vehicle **36**. The transmitter **14** can be in contact with the dash, trunk, cabin, ceiling, or engine compartment of the vehicle **36**.

[0054] The present invention pertains to an adjustable RF power transmitter **14** for powering wirelessly an RF power harvesting device **12**, as shown in FIG. **3**. The transmitter **14** comprises a housing **40** having outer dimensions no greater than 3"×3" by 8 inches. The transmitter **14** comprises a power input **42**. The transmitter **14** comprises a frequency generator **44** in communication with the power input **42**. The transmitter **14** comprises an amplifier **46** in communication with the frequency generator **44**. The transmitter **14** comprises a controller **48** connected with the frequency generator **44**. The transmitter **14** comprises an antenna **50** connected to the amplifier **46**.

[0055] The transmitter **14** can include a circuit board **52** on which the power input **42**, the frequency generator **44** and the amplifier **46** are disposed. The transmitter **14** can include a heat sink **54** in contact with the circuit board **52**. The transmitter **14** can include a fan **56** disposed adjacent the circuit board **52**.

[0056] The present invention pertains to a power transmission system **10** for wirelessly powering an RF power harvesting device **12**, as shown in FIG. **13**. The system **10** comprises a computer **58** with an antenna **50**. The system **10** comprises an RF transmitter **14** in communication with the antenna **50**. The system **10** comprises a power supply **60** in electrical communication with the RF transmitter **14** and the computer **58**.

[0057] Preferably, the RF transmitter **14** is connected to the computer **58**. The computer **58** can have a power port **64**, and the transmitter **14** is plugged into the power port **64**. The power port **64** can be a USB port **64**. The antenna **50** can be integrated with the transmitter **14**. Alternatively, the system **10** can include a display **62**, and the antenna **50** is in contact with the display **62**.

[0058] The present invention pertains to an apparatus **80** for wirelessly powering a power harvesting device **12**, as shown in FIG. **8**. The apparatus **80** comprises at least one RF power transmitter **14**. The apparatus **80** comprises a lighting fixture **26** in which the transmitter **14** is disposed and from which the transmitter **14** receives power.

[0059] The lighting fixture **26** can be a fluorescent lighting fixture **26**. The lighting fixture **26** can be an incandescent lighting fixture **26**. The lighting fixture **26** can be an LED lighting fixture **26**. The apparatus **80** can include a light source in electrical communication with the lighting fixture **26**.

[0060] The present invention pertains to a power transmission system **10** for wirelessly powering a power harvesting device **12**, as shown in FIG. **15**. The system **10** comprises at least one RF power transmitter **14**. The system **10** comprises a track **66** supplying power to which the transmitter **14** is electrically connected.

[0061] Preferably, there are at least two power transmitters **14**. The system **10** can include at least two lights **22** electrically connected to the track **66**. The track **66** can include a first conductor **68** and a second conductor **70**, as shown in FIGS. **16**_a_-**16**_d_. The track **66** may include a support **72** attached to a wall or ceiling, as shown in FIG. **17**.

[0062] The present invention pertains to a power transmission system **10** for wirelessly powering a power harvesting device **12**, as shown in FIG. **12**. The system **10** comprises at least one RF power transmitter **14**. The system **10** comprises a battery **74** charging unit to which the transmitter **14** is electrically connected.

[**0063**] The present invention pertains to a power transmission system **10** for wirelessly powering a power harvesting device **12**, as shown in FIG. **14**. The system **10** comprises at least one RF power transmitter **14**. The system **10** comprises at least one rechargeable battery **74** to which the transmitter **14** is electrically connected.

[**0064**] The system **10** can include a second RF power transmitter **14'** which transmits power to the power harvesting device **12** electronically connected to the battery **74**. A valve sensor **76** can include the valve sensor **76'** powered by a power harvesting device **12'**. The system **10** can include an RF power repeater **78**.

[**0065**] The present invention pertains to a method for wirelessly powering a power harvesting device **12**. The method comprises the steps of electrically connecting at least one RF power transmitter **14** to an AC power grid **16**. There is the step of transmitting power with the RF power transmitter **14**.

[**0066**] The present invention pertains to a method for wirelessly powering a power harvesting device **12**. The method comprises the steps of electrically connecting at least one RF power transmitter **14** to a DC power grid **30**. There is the step of transmitting power with the RF power transmitter **14**.

[**0067**] The present invention pertains to a method for wirelessly powering a power harvesting device **12**. The method comprises the steps of electrically connecting a power supply **60** with an RF transmitter **14** and a computer **58**. There is the step of transmitting power with the RF power transmitter **14**.

[**0068**] The present invention pertains to a method for wirelessly powering a power harvesting device **12**. The method comprises the steps of electrically connecting at least one RF power transmitter **14** with a lighting fixture **26** in which the transmitter **14** is disposed and from which the transmitter **14** receives power. There is the step of transmitting power with the RF power transmitter **14**.

[**0069**] The present invention pertains to a method for wirelessly powering a power harvesting device **12**. The method comprises the steps of electrically connecting at least one RF power transmitter **14** to a battery **74** charging unit. There is the step of transmitting power with the RF power transmitter **14**.

[**0070**] The present invention pertains to a power transmission system **10** for wirelessly powering a power harvesting device **12**. The system **10** comprises at least one RF power transmitter **14**. The system **10** comprises means for providing power to which the transmitter **14** is electrically connected.

[**0071**] The means can be an AC power grid **16**, a DC power grid **30**, a battery **74** or any other power sources identified herein.

[**0072**] The present invention pertains to an apparatus **80** for wirelessly powering a power harvesting device **12** from a DC power outlet **18** of a vehicle **36**, as shown in FIG. **11**. The apparatus **80** comprises an RF power transmitter **14**. The apparatus **80** comprises a power plug **82** to which the transmitter **14** is attached and electrically connected that plugs into the DC power outlet **18**.

[**0073**] The present invention pertains to an apparatus **80** for wirelessly powering a power harvesting device **12** from an AC power grid **16** having an AC power outlet **18**, as shown in FIG. **1**. The apparatus **80** comprises an RF power transmitter **14**. The apparatus **80** comprises a power plug to which the transmitter **14** is electrically connected that electrically connects with the AC power outlet **18**.

[**0074**] The present invention pertains to an apparatus **80** for wirelessly powering a power harvesting device **12** from a DC power outlet **18** of a DC grid **30**, as shown in FIG. **2**. The apparatus **80** comprises an RF power transmitter **14**. The apparatus **80** comprises a power plug to which the transmitter **14** is electrically connected that electrically connects with the DC power outlet **18**.

[**0075**] The present invention pertains to an apparatus **80** for wirelessly powering a power harvesting device **12** from a computer **58** having an antenna **50** and a power supply, as shown in FIG. **13**. The apparatus **80** comprises an RF power transmitter **14**. The apparatus **80** comprises a power plug to which the transmitter **14** is electrically connected that electrically connects with the computer **58**.

[**0076**] The present invention pertains to an apparatus **80** for wirelessly powering a power harvesting device **12** from a light fixture **26**, as shown in FIG. **5**. The apparatus **80** comprises an RF power transmitter **14**. The apparatus **80** comprises an electrical interface to which the transmitter **14** is electrically connected that electrically connects with the light fixture **26**.

[**0077**] The present invention pertains to an apparatus **80** for wirelessly powering a power harvesting device **12** from a track **66** having at least one light **22**, as shown in FIG. **15**. The apparatus **80** comprises an RF power transmitter **14**. The apparatus **80** comprises an electrical interface to which the transmitter **14** is electrically connected that electrically connects with the track **66**.

[**0078**] The present invention pertains to an apparatus **80** for wirelessly powering a power harvesting device **12** from a battery **74** charging unit, as shown in FIG. **14**. The apparatus **80** comprises an RF power transmitter **14**. The apparatus **80** comprises an electrical interface to which the transmitter **14** is electrically connected that electrically connects with the battery **74** charging unit.

[**0079**] The design of a Radio-Frequency (RF) Power Transmitter and an RF Power Network have been described in detail in U.S. patent application Ser. No. 11/356,892, “Pulse Transmission Method”, U.S. continuation-in-part patent application Ser. No. 11/651,818, “Pulse Transmission Method”, U.S. provisional application Ser. No. 11/438,508, “Power Transmission Network”, and U.S. provisional continuation-in-part application 60/833,864, “Power Transmission Network and Method”, all incorporated by reference herein. The referenced patents give great detail on how an RF Power Transmitter and an RF Power Network can be constructed for various transmitter and antenna **50** combinations. It, however, also becomes advantageous, and the focus of the invention, to describe how the RF Power Transmitters **14** and RF Power Network derive the power used for operating the components necessary to both such as, but not limited to, transmitter(s) **14**, controller(s) **48**, and/or antenna(s) **50**. It should be noted that an RF Power Network is made up of more than one RF power transmitter **14** where the coverage areas **38** may or may not overlap and the RF power transmitter **14** includes one or more antenna **50** for transmitting the generated RF power which may be pulsed or continuous. It should also be noted that RF power transmitters **14** and RF power networks may be used to directly power one or more RF harvesting devices or charge, recharge, or trickle charge a power storage component. An RF power receiver such as, but not limited to, the RF power receivers described in U.S. provisional application **11/584, 983**, "Method and Apparatus for High Efficiency Rectification for Various Loads", may be used with the presented invention although any RF harvesting device may be used. It should be noted that a device containing RF harvesting circuitry may be referred to herein as an RF harvesting device, an RF power harvesting device **12**, or an RF power receiver. Additionally, the apparatus **80**, with or without the receiving antenna **50**, for converting the RF energy to a usable form such as, but not limited to, direct current (DC), may be referred to herein as the RF harvesting circuitry, RF power harvester, or RF power receiver.

[0080] It should be noted that the RF power transmitters **14** and RF power network in the invention should not be confused with RF power transmitters **14** using inductive coupling, which requires the device to be relatively close to the power transmission source. The RFID Handbook by the author Klaus Finkenzeller defines the inductive coupling region as distance between the transmitter **14** and receiver of less than 0.16 times lambda where lambda is the wavelength of the RF wave. The proposed invention can obtain power in the near field (sometimes referred to as inductive) region as well as the far-field region. The far-field region is distances greater than 0.16 times lambda.

[0081] One method for obtaining power for an RF power transmitter **14** and/or RF power network would be to hardwire the RF power transmitter **14** or RF power network to an Alternating Current (AC) power grid or source used to supply power to lights, outlets, and other devices with voltages from 100 to 240 volts. This may be the ideal choice for new construction projects where the wiring can be easily accessed and the RF power transmitters **14** can be installed along with the wiring, lighting fixtures **26**, switches, and outlets. The RF power transmitter **14** and/or RF power network may then contain an AC to DC converter **28** that can convert the AC power obtained from the AC power main or source to a usable DC voltage (or current) such as but not limited to 3.3 to 48 volts. An example of this transmitter **14** and network implementation is shown in FIG. **1**. It should be noted that the RF power transmitter(s) **14** and/or RF power network may be hardwired to a DC network or source, if available, and, if needed, the RF power transmitter(s) **14** and/or RF power network may use a DC to DC converter to obtain the correct operational voltage. An example of a DC network or source includes, but is not limited to, the wiring within an automobile, car, truck, van, recreational vehicle, bus, public transportation, commercial truck, commercial equipment, construction equipment, industrial equipment, farm equipment, airplane, boat, ship, submarine, computer **58**, or any other manned or unmanned apparatus **80** containing a DC network or source. As an example, an RF power transmitter **14** may be hardwired to the 12 volt DC network or source within an automobile. At least one RF power transmitter **14** may be installed in the engine compartment, dash, ceiling, cabin, or trunk of the automobile to provide RF power to RF power harvesting devices **12** inside or outside (if within the coverage area **38**) of the automobile. The RF power harvesting devices **12** may include, but are not limited to, cellular phones, cellular phone accessories, car phones, voice communicating devices, PDAs, music players, laptops, toys, car sensors, or other devices that may require power.

[0082] As an example, an RF power transmitter **14** may be mounted on a utility pole **32** and hardwired to the AC power grid **16** in order to provide RF power to RF energy harvesting devices within the coverage area **38**. Multiple RF power transmitters **14** may be implemented in order to provide an RF power network.

[0083] As a specific example, at least one RF power transmitter **14** may be implemented by direct hardwiring to the DC network in the dashboard of an automobile in order to charge a cellular phone containing RF power harvesting circuitry while the cellular phone is inside the automobile or outside the automobile but still within the coverage area **38** of the RF power transmitter **14**. The coverage area **38** for the automobile in this example would be designed to give coverage over the cabin of the automobile as shown in FIG. **2**. For most automobiles, the coverage area **38** would have a range of 6 to 8 feet from the RF power transmitter **14**. The coverage area **38** is defined by a minimum electric and/or magnetic field strength produced by the RF power transmitter **14**. The range of the RF power transmitter **14** or coverage area **38** is defined as the distance from the RF power transmitter **14** to the outer limit of the coverage area **38** for a specific angle with respect to the RF power transmitter **14**. The coverage area **38** may take on different shapes and sizes and is dependent on numerous factors including, but not limited to, the RF power transmitter **14** power level, the gain and radiation pattern of the RF power transmitting antenna **50**, the environment, and the power needs of the RF power harvesting devices **12** in the coverage area **38**. For an automobile, it may be necessary to provide 1 milli-watt (mW) of power to an RF power harvesting device **12** within the cabin having a maximum range of six feet. If omnidirectional antennas **50** are used by the RF power transmitter **14** and the RF harvesting circuit at 915 mega-Hertz (MHz), the RF power transmitter **14** would need to supply 2 Watts (W) of power to the RF power transmitting antenna **50** in order to supply the needed power to the RF power harvesting device **12** at a range of six feet. An RF power transmitter **14** has been designed and constructed to meet these requirements. The adjustable RF power transmitter **14** is capable of transmitting 0.25 W to 20 W of power as a continuous-wave (CW) or as a pulsed-wave (PW). The transmitter **14** has outside dimensions of 1.5×1.5×4.775 inches as shown in FIG. **3**. The omnidirectional antennas **50** at 915 MHz may be implemented with half-wave dipoles that have a length of 6 inches and a diameter of 0.1 inches.

[0084] It should be noted that the RF power transmitter **14** shown in FIG. **3** may be used with any of the embodiments herein if found to be advantageous. The RF power transmitter **14** may contain a power input **42** for accepting AC or DC power, a frequency generator **44** for generating the appropriate frequency(ies), an amplifier **46** and/or preamplifier for adjusting the output power (gain or attenuation), a controller **48** for controlling the amplifier **46** and frequency generator **44**, a heat sink **54** for dissipating heat from or cooling the RF power transmitter **14**, a fan **56** for providing air flow through or across the heat sink **54** and/or printed circuit board **52** for cooling, a printed circuit board **52** (PCB) for component mounting, and an RF output connection for supplying the RF power to the RF power transmitting antenna **50**. The RF power transmitting antenna **50** may also be integrated onto the PCB.

[0085] It should be noted that one or more antennas **50** may be used with the invention and the antennas **50** may have omnidirectional or directional radiation patterns and may be designed to have linear, circular, elliptical, dual, or any other type of polarization that may be advantageous to the RF power system **10**.

[0086] For the case of a DC network or source with a computer **58**, an RF power transmitter **14** may be hardwired to the **12**-volt power supply **60** in order to supply RF power to devices located in or around the computer **58**. The computer **58** may have one or more antennas **50** located internally or externally in communication with the RF power transmitter **14**. As an example, the RF power transmitter **14** may be located in the computer **58** case while the antennas **50** are mounted in or on the monitor or display. The monitor may have two antennas **50**, one on each side of the screen in order to give a better coverage area **38** or network. The antennas **50** may be connected to the computer **58** case using one or two coaxial cables or the RF power may be supplied through a conductor in the monitor cable. As a specific example, the RF power transmitter **14** may have dimensions of 5.75 by 6.69 by 1.63 inches allowing the RF power transmitter **14** to fix into a bay within the computer **58** tower typically used for CD-ROM and DVD drives. The RF power transmitter **14** may accept a plug **82** from the computer **58** power supply **60**. The RF power transmitting antenna **50** may be external to the computer **58** tower or may be formed on the front of the RF power transmitter **14**. Additionally, the RF power transmitter **14** may be in communication internally with the computer **58** or part of the computer **58** for control of the RF power transmitter **14** or for controlling communication with RF power harvesting devices **12** receiving RF power from the RF power transmitter **14**. The RF power transmitter **14** may also be formed as a card designed to plug into standard computer **58** or laptop slots such as, but not limited to, PCI bus slots, AGP slots, PCI express slots, ISA slots, PCMCIA slots, or any other computer **58** or laptop slot. In certain applications, the RF power transmitter **14** may also be formed on the motherboard of the computer **58** with the RF power antenna **50** being internal or external to the computer **58** tower.

[0087] Additionally, the RF power transmitters **14** may be recessed or flush mounted like an AC or DC outlet **18** or switch, or may replace, or be used in conjunction, with an AC or DC outlet **18** whether existing or specialized to include an RF power transmitter **14** and RF power antenna **50**. An example of this can be seen in FIG. **4** where the AC outlet **18** from FIG. **1** has been replaced with the RF power transmitter **14**. The RF power transmitter **14** is mounted flush with the wall. In this example, the box retains the function of providing AC power to devices that plug into it, but also transmits RF power through an RF power antenna **50** that is mounted behind the wall. Furthermore, the RF power transmitter **14** may fit completely into a standard junction box **34** with the RF power antenna **50** being internal or the antenna **50** may be connected outside the junction box **34** by a connector exiting through the junction box **34** or junction box **34** cover. The RF power transmitter **14** may have dimensions of 3.8 by 3.8 by 2.1 inches in order to fit in a junction box **34**, and the RF power transmitting antenna **50** may have a length of 6 inches and a diameter of 0.1 inches for a 915 MHz RF power transmitter **14**. In certain instances the cover of the junction box **34** could be or contain the RF power antenna **50**. It may also be possible to embed the RF power transmitter **14** and/or RF power antenna **50** on or in, partially or completely, the material of the structure that the RF power transmitter **14** and/or RF power antenna **50** are mounted to, in, or behind, depending on the attenuating properties of the material. The RF power transmitter **14** and/or RF power antenna **50** may also be located behind the material to eliminate the need for an opening in the material for the RF power transmitter **14** and/or RF power antenna **50** to protrude through. As an example, the RF power transmitter **14** and RF power antenna **50** may be implemented by direct connection to the AC power main or source and be completely located behind a low attenuation wall at the frequency of the RF power transmitter **14**.

[0088] In cases of an existing structure or an implementation requiring a simpler installation, it may be advantageous to develop additional methods for deriving the power for the RF Power Transmitter **14** and/or RF Power Network. As an example, in an existing building it may be necessary to access wiring inside the walls or ceiling in order to hardwire the RF power transmitter(s) **14** to the AC power main which may require that an opening be made and repaired. The destruction and construction required for the opening in the wall may require building permits and trained or experienced personal such as an electrician, carpenter, or other contractor. This process may not be an attractive solution for certain implementations. Therefore, it becomes necessary to develop additional methods other than direct hardwiring of the RF power transmitter(s) **14**. One such method is to design a transmitter **14** that can be used in conjunction with an existing lighting fixture **26**, lamp, or other power receptacle for a light source. A light source may include, but is not limited to, a light bulb, an incandescent light, a fluorescent bulb, a fluorescent lamp, a halogen bulb, a light-emitting diode (LED), an organic light-emitting diode (OLED), a full spectrum bulb, or any other light producing device. As an example, a transmitter **14** could be constructed in a fashion that would enable it to screw or plug into an existing lighting fixture **26**, lamp, or other power receptacle for a light **22** source using a standard or custom base, such as but not limited to, Candelabra/E12, Intermediate/E17, Medium/E26, Mogul/E39, Bayonet, (T8) Medium Bi-Pin, (T12) Medium Bi-Pin, (T5) Miniature Bi-Pin, or any other type of connector used to connect the light **22** source to the AC or DC power main. The resulting transmitter **14** would replace the light **22** source to provide coverage of RF power rather than light **22** where the RF energy could be used to deliver power to devices containing RF power harvesting circuitry. An example of this invention can be seen in FIG. **5**. In this example, the RF power transmitter **14**, like the light **22** source it is replacing, protrudes from the lighting fixture **26**, but in some cases the, the RF power transmitter **14** may be recessed into the fixture. The RF power transmitter **14** may have dimensions of 1.6 by 1.6 by 4 inches in order to fit in a lighting fixture **26**, and the

RF power transmitting antenna **50** may have a length of 6 inches and a diameter of 0.1 inches for a 915 MHz RF power transmitter **14**.

[**0089**] When implementing an RF power transmitter **14** solely or within an RF power network, it may not always be practical to completely remove the light **22** source from the lighting fixture **26**, lamp, or other power receptacle for a light **22** source. In this case, the transmitter **14** could, as previously described, screw or plug into the existing lighting fixture **26**, lamp, or other power receptacle for a light **22** source and also include the ability to accept a light **22** source with a standard or custom base, such as but not limited to, Candelabra/E12, Intermediate/E17, Medium/E26, Mogul/E39, Bayonet, (T8) Medium Bi-Pin, (T12) Medium Bi-Pin, (T5) Miniature Bi-Pin, or any other type of connector used to connect the light **22** source to the AC or DC power main. The ability to accept a light **22** source allows the lighting fixture **26**, lamp, or other power receptacle for a light **22** source to contain an RF power transmitter **14** and a light **22** source meaning the lighting fixture **26**, lamp, or other power receptacle for a light **22** source can perform its primary function of supplying light **22** while also performing a secondary function of providing RF power to devices containing RF power harvesting circuitry. An example of this method can be seen in FIG. **6**. It should be noted that the type of base in the lighting fixture **26**, lamp, or other power receptacle for a light **22** source may be different than the type of base in the RF power transmitter **14** that accepts the light **22** source. More specifically, the lighting fixture **26**, lamp, or other power receptacle for a light **22** source may have a Mogul/E39 base while the RF power transmitter **14** accepts a light **22** source with a Medium/E26 base. Additionally, the lighting fixture **26**, lamp, or other power receptacle for a light **22** source may be recessed into the ceiling, wall, or mounting surface. The RF power transmitter **14** may have dimensions of 4 by 4 by 1 inch in order to fit into a recessed lighting fixture **26** that accepts a light bulb, and the RF power transmitting antenna **50** may have a length of 6 inches and a diameter of 0.1 inches for a 915 MHz RF power transmitter **14**.

[**0090**] To simplify the previous example, the light **22** source could be integrated into the RF power transmitter **14** to allow the light **22** source and RF power transmitter **14** to work in conjunction with one another as shown in FIG. **7**. As an example, the antenna **50** of the RF power transmitter **14** could be formed from part of metal contained within the existing light **22** source or the antenna **50** could be integrated into or onto the light **22** source as a custom solution. The antenna **50** may be formed by depositing metal or any other conductive material on the glass of the light **22** source to form a resonant antenna **50** structure. The conductive material may have transparent or semi-transparent properties to allow light **22** to pass through the antenna **50** structure. A transparent antenna **50** may be formed using a material such as, but not limited to, Indium Tin Oxide. The antenna **50** may also be formed inside the light **22** source if found to be advantageous. In cases where a directional light **22** source is used to focus the light **22** to a specific area using a light **22** reflective surface, the antenna **50** could use the reflective surface, if metallic, to also reflect or focus the RF energy transmitted from the antenna **50**. It may become necessary to use a long-life light **22** source such as an LED to reduce the amount of maintenance on each lighting fixture **26**, lamp, or other power receptacle for a light **22** source. When the light **22** source or RF power transmitter **14** cease normal operation, the RF power transmitter **14** and light **22** source combination can be easily replaced by unscrewing or unplugging the RF power transmitter **14** with integrated light **22** source. The used device may be repaired or simply discarded depending on the application. It should be noted that the RF power transmitter **14** and light **22** source combination may be recessed into the lighting fixture **26**. The RF power transmitter **14** with integrated light **22** source may have dimensions of 4 by 4 by 6 inches in order to fit into a recessed lighting fixture **26**, and the RF power transmitting antenna **50** may have a length of 6 inches and a diameter of 0.1 inches for a 915 MHz RF power transmitter **14**.

[**0091**] In the two previous implementations, the RF power transmitter **14** accepted or had a built-in light **22** source. In certain applications, the RF power transmitter **14** may be integrated into an existing or specialized lighting fixture **26**. As an example, typical lighting in an office building is provided by lighting fixtures **26** containing four four-foot fluorescent lights. This type of lighting fixture **26** may be retrofitted with at least one RF power transmitter **14** or the lighting fixture **26** may be redesigned to contain at least one RF power transmitter **14**. An example of this can be seen in FIG. **8**. As an additional example, an RF power transmitter **14** may be used in conjunction with an existing or specialized light bulb and/or fixture within a street light for the purpose of providing power to RF power harvesting devices **12** within the coverage area **38** defined by one or more street lights. Additionally, an RF power transmitter **14** may be implemented with landscape, exterior, emergency, specialty, automobile, or any other type of lighting fixture **26** or light **22** producing source. For the case of the automobile, an RF power transmitter **14** may be implemented with or within the interior lights or headlights to provide RF power to devices within the resulting coverage area **38**.

[**0092**] Another way of implementing an RF power transmitter **14** and/or RF power network is to connect the transmitter(s) **14** to existing outlets **18**, receptacles, ports, or connectors within a building, automobile, device or structure by a plug **82** and cord **20** that can be used to provide AC or DC directly from the outlet **18**. In most cases for an AC power grid **16** or source, the DC power may be obtained from an AC to DC converter **28** located at the outlet **18**, receptacle, port **64**, connector or somewhere between the outlet **18**, receptacle, port **64**, or connector and RF power transmitter **14**. As an example, an RF power transmitter **14** and/or RF power network may be designed to give coverage over a desk, a room, an entire home, an entire building floor, the entire building, or an automobile. The coverage area **38** is defined by a minimum electric and/or magnetic field strength produced by the RF power transmitter **14**. As in the case of the desk or room, a single RF power transmitter **14** may be sufficient to give coverage over the required area. Therefore, the RF power transmitter **14** may be designed to plug into an existing outlet **18** near the desk or somewhere within the room. The ability to have a cord **20** gives flexibility to the RF power network design by allowing the use of an existing AC or DC outlet **18** with the ability to place the RF power transmitter **14** away from the AC or DC outlet **18**. As an example, it may be necessary to provide RF power coverage over a bedroom in order to recharge a medical implant within a patient while they are located within their bedroom. The RF power transmitter **14** can then be located on the nightstand or can be attached to the headboard in order to supply RF power to the medical implant to recharge the implant's battery **74** or power storage component. The RF power transmitter **14** can obtain its operational power by plugging into one of the AC outlets **18** in the room where the AC outlet **18** may be located several feet from the RF power transmitter **14** location as shown in FIG. **9**. Several RF power transmitters **14** have been designed at 915 MHz that plug into an existing AC outlet **18** using a power cord **20**. The first RF power transmitter **14** had dimensions of 2.6 by 4.25 by 1.26 inches and an output power of 0.5 W while the second had dimensions of 4.4 by 6.4 by 2 inches and an output power of 5 W. The RF power transmitting antenna **50** for the first transmitter **14** was a monopole with a length of 3 inches while the second RF power transmitting antenna **50** was a dipole and had a length of 6 inches and a diameter of 0.1 inches.

[0093] For the case of an automobile, the RF power transmitter **14** may plug into the 12V DC power outlet **18** or cigarette lighter outlet **18** through a cord **20** and the RF power transmitter **14** may then be placed on the dash or the center console in order to provide RF power to devices containing RF power harvesting circuitry in the coverage area **38** provided by the RF power transmitter **14** and RF power antenna **50**.

[0094] For the case of a computer **58**, the RF power transmitter **14** may plug into existing or specialized computer **58** ports **64**, such as, but not limited to, USB, serial, parallel, FireWire, or any other power carrying port **64**, through a cord **20** in order to supply power to an RF power transmitter **14**.

[0095] It should be noted that an RF power transmitter **14** may plug into other devices, directly or with a cord **20**, such as, but not limited to, a console gaming system, computer **58**, laptop computer **58**, or any other device have an outlet **18**, receptacle, port **64**, or connector that may be used to obtain power for an RF power transmitter **14**.

[0096] It should also be noted that any of the RF power transmitters **14** described herein may have the ability to supply power to other devices by having an outlet. **18**, receptacle, port **64**, or connector that may be the same or a different type than the one supplying the RF power transmitter **14**. As an example, an RF power transmitter **14** being powered from a USB or Ethernet port **64** may have a USB or Ethernet port **64** to allow other devices to use the same USB or Ethernet port **64** as the RF power transmitter **14**.

[0097] In certain applications, it may not be necessary to run a cord **20** from the outlet **18**, receptacle, port **64**, or connector to the RF power transmitter **14**. The AC or DC outlet **18**, receptacle, port **64**, or connector may be positioned in a location that provides the required RF energy coverage when the RF power transmitter **14** is located at the location of the outlet **18**, receptacle, port **64**, or connector. In these cases, the RF power transmitter **14** can simply plug into the outlet **18**, receptacle, port **64**, or connector without the need for an extension cord **20**. The RF power transmitter **14** may be supported in whole or part by the friction created from the AC or DC prongs inserted into the outlet **18**, receptacle, port **64**, or connector. Additionally, the RF power transmitter **14** may pass the AC or DC power to at least one AC or DC outlet **18**, receptacle, port **64**, or connector located on the RF power transmitter **14** in order to enable other devices to plug into the AC or DC main or source through the RF power transmitter **14**. The RF power transmitter **14** may have one or more antenna **50** that are used to radiate and/or direct the RF power away from the outlet **18**, receptacle, port **64**, or connector to an RF power receiving device containing RF power harvesting circuitry which can harvest the available RF power to power a device or charge or recharge a charge storage component such as a battery **74**, capacitor, or other charge storage component. FIG. **10** shows an example of an RF power transmitter **14** that plugs directly into an AC outlet **18**. An RF power transmitter **14** plugging directly into an AC outlet **18** may have dimensions of 2.6 by 4.25 by 1.26 inches, and the RF power transmitting antenna **50** may have a length of 6 inches and a diameter of 0.1 inches for a 915 MHz RF power transmitter **14**.

[0098] For the case of an automobile, the RF power transmitter **14** may plug directly into the 12V DC power outlet **18** or cigarette lighter outlet **18** without the need for a cord **20** in order to provide RF power to devices containing RF power harvesting circuitry in the coverage area **38** provided by the RF power transmitter **14** and RF power antenna **50**. An example of an RF power transmitter **14** that plugs directly into the DC power outlet **18** of an automobile can be seen in FIG. **11**. An RF power transmitter **14** plugging directly into a DC outlet **18** may have dimensions of 2 by 2 by 1 inch, and the RF power transmitting antenna **50** may be internal or external to the RF power transmitter **14** and have a length of 6 inches and a diameter of 0.1 inches for a 915 MHz RF power transmitter **14**.

[0099] For the case of a computer **58**, the RF power transmitter **14** may plug directly into existing or specialized computer **58** ports **64**, such as, but not limited to, USB, serial, parallel, FireWire, or any other power carrying port **64**, in order to supply power to an RF power transmitter **14**.

[0100] It may be beneficial in certain applications to include a battery **74** charger or power storage component charger with the RF power transmitter **14**. This solution is of particular interest when the RF power harvesting device **12** may require more power than the RF power transmitter **14** or RF power network can provide or if the RF power harvesting device **12** needs to obtain a fast charge such as when the battery **74** voltage level has fallen below the minimum threshold for operation of the device. The battery **74** or other charge storage component that is normally charged or recharged from the RF power transmitted by the RF power transmitters **14** and/or RF power network could be removed from the device and placed in the battery **74** or charge storage component recharger built-in to the RF power transmitter **14** for a faster charging where the recharger is powered directly by the AC or DC power main. A battery **74** or charge storage component charger could be included in any of the implementations described in this document. An example of including a battery **74** charger with an RF power transmitter **14** is shown in FIG. **12** for the case of the RF power transmitter **14** that directly plugs into an AC outlet **18**. An RF power transmitter **14** with a battery **74** charger plugged directly into an AC outlet **18** may have dimensions of 2.6 by 4.25 by 1.26 inches, and the RF power transmitting antenna **50** may have a length of 6 inches and a diameter of 0.1 inches for a 915 MHz RF power transmitter **14**.

[0101] For the case of an automobile, the RF power transmitter **14** may plug directly into the 12V DC outlet **18**

or may have a cord **20** and the RF power transmitter **14** may then be placed on the dash or the center console in order to provide RF power to devices containing RF power harvesting circuitry in the coverage area **38** provided by the RF power transmitter **14** and RF power antenna **50**. Additionally, the RF power transmitter **14** may contain a battery **74** charger or charge storage component charger in order to obtain a faster charge cycle. The charger may be designed to accept standard battery **74** sizes such as AA, AAA, C, and/or D cell batteries or may be designed to accept a product specific battery **74** that may or may not be attached to the device at the time of charging. As an example, a cellular phone may contain RF power harvesting circuitry for capturing RF power when within the coverage area **38** provided by the RF power transmitter **14**. The RF power transmitter **14** may also contain a cradle with charging connections that would allow the cellular phone to be directly charged by a hardwired connection in order to obtain a faster charge.

[**0102**] In certain applications, the RF power transmitter **14** may obtain operational power from a battery **74** or charge storage component in order to transmit RF power. The battery **74** or charge storage component may include, but is not limited to, rechargeable batteries, capacitors, fuel cells, generators, other charge storage components, or other charge generating components. In some cases, the RF power transmitter **14** may draw its power from a battery **74** or charge storage device that is supplying power to other devices simultaneously. For example, a laptop computer **58** uses a battery **74** for operational power. An RF power transmitter **14** could be attached with or without a cord **20** to the laptop computer **58**, by means disclosed herein such as through the USB port **64** of the laptop computer **58**, and would use the same battery **74** for operational power that the laptop computer **58** is using. An example of the RF power transmitter **14** directly connected to a computer **58** is shown in FIG. **13**. The RF power transmitter **14** could then supply power to computer **58** peripherals or other devices within its coverage area **38**, such as, but not limited to, keyboards, mice, game controllers, cellular phones, cellular phone accessories, PDAs or other peripherals or devices that are designed with RF power harvesting circuitry. An RF power transmitter **14** plugging directly into the USB or other port **64** of a computer **58** may have dimensions of 3 by 0.75 by 0.75 inches, and the RF power transmitting antenna **50** may be integrated with the RF power transmitter **14**.

[**0103**] In certain applications, the battery **74** or charge storage component used to run the first RF power transmitter **14** may be receiving power from a second RF power transmitter **14** for the purpose of charging the battery **74** or charge storage element in the first RF power transmitter **14**. Power for the second RF power transmitter **14** may be obtained from an AC or DC power network or by other means described herein. As an example, it may be necessary to supply power to an RF power-harvesting device, which is located in a position that does not allow direct line-of-sight or a low attenuation transmission path. As a specific example, an RF power transmitter **14** may be required to supply power to a valve sensor **76** in an industrial application. However, the AC power grid **16** used for obtaining operational power for the RF power transmitter **14** may be located on one side of a large metal storage tank while the valve sensor **76** requiring power may be located on the opposite side. In order to obtain sufficient power at the valve sensor **76**, an additional RF powered RF power transmitter **14** may be required in order to direct, relay, or bounce the power around the metal storage tank as shown in FIG. **14**. The RF powered RF power transmitter **14** may be an RF power transmitter **14** also containing an RF power harvesting device **12** or may be implemented with a passive RF repeater **78**. The passive RF repeater **78** receives the power with one antenna **50** and passes the RF power to a second antenna **50**, which retransmits the power in a different direction.

[**0104**] When deploying multiple RF power transmitters **14** in an RF power network, it becomes necessary to develop a method that allows the installer or user to easily and quickly install or add RF power transmitters **14** to the RF power network. One solution is to build an RF power transmitter **14** that can be installed into the track **66** of existing track **66** lighting. The RF power transmitters **14** can then be easily retrofitted into existing structures or places containing track **66** lighting. The RF power transmitter **14** can simply snap or screw into the track **66** to obtain AC or DC power depending on the type of track **66** lighting. The power track **66** could then contain both lights **22** and RF power transmitters **14** although the track **66** may contain only RF power transmitters **14**. It should be noted that the track **66** may contain RF power transmitters **14** that accept or have built-in light **22** sources as previously described herein.

[**0105**] It is also possible to develop a specialized type of track **66** that allows the tracks **66** to be concatenated with track **66** junctions to incorporate a large number of RF power transmitters **14** in order to cover a large area. The tracks **66** may be, but are not limited to, six feet in length. The track **66** junctions may contain, but are not limited to, a connector (whether a plug **82**, snap, or clip) or a slip-in fitting in order to concatenate tracks **66** to obtain longer lengths. It is also possible to design a track **66** junction that could be used to connect two or more tracks **66** together by connectors or slip-in fittings in order to change the direction of the track(s) **66** or to connect multiple tracks **66**. Additionally, it is possible to design an RF power transmitter **14** that can be used as an RF power transmitter **14** and a track **66** junction. An example of a track **66** system for implementation of an RF power network can be seen in FIG. **15**. It should be noted that the track **66** may contain light **22** sources.

[**0106**] Each track **66** may contain at least two conducting portions in order to provide an input and return for the AC or DC power for the RF power transmitters **14**. As an example for an AC main implementation, the input line is the AC hot wire, typically the black wire, and the return line is the AC neutral wire, typically the white wire. The track **66** and supporting structure, if metal, may be connected to the AC ground for safety purposes. There may also be a ground wire and a wire used for communicating between the RF power transmitters **14** in order for an RF power transmitter **14** to obtain information about other RF power transmitters **14** operations such as, but not limited to, pulse timing, polarization, frequency, power level, transmission algorithm, antenna **50** gain, or other pertinent information. The communication between the RF power transmitters **14** may be done by, but not limited to, a microcontroller integrated in the RF power transmitter **14** with each having a unique identification or a master/slave configuration. It should be noted that for large implementations of RF power transmitters **14**, it may become necessary to split the communicating portion of the network into multiple smaller networks which could be accomplished with, but not limited to, a special track **66** junction that only passes the AC or DC power and isolates the communication conductors.

[**0107**] The tracks **66** used for the invention can take many different forms. The proposed invention can be implemented with any type including, but not limited to, snap-in tracks **66**, screw-in tracks **66**, sliding tracks **66**, concatenatable tracks **66**, AC tracks **66**, DC tracks **66**, or any other track **66** that can supply current to at least one RF power transmitter **14**. It should be noted that the track **66** may take on various shapes including, but not limited to, those shown in FIG. **16**.

[**0108**] One track **66** that is particularly advantageous is the coated cable shown in FIG. **16***c*. One cable is the input path while the other cable acts as the return path. The cable could be used to supply either AC or DC power to the RF power transmitter **14** although DC would have numerous advantages due to safety issues, fire concerns, and building regulations. The RF power transmitters **14** could be set on top of the cable, which would supply power and support the RF power transmitters **14**. The RF power transmitters **14** could have at least one screw for each cable in order to secure the RF power transmitter **14** to the cable and to pierce the non-conducting protective coating on the outside of the conducting cable. An example of an RF power transmitter **14** connected to the cable track **66** system **10** can be seen in FIG. **17**. It should be noted that additional cables could be used for, but not limited to, ground, communication, or some other signal if found to be advantageous. As with the network shown in FIG. **15**, the cable track **66** system **10** could be used to provide coverage over a hallway or hallways. The main advantage of the cable track **66** system **10** is its easy installation. The cable may be a large spool of cable allowing long runs of track **66** without the need for track **66** junctions. It is also possible to implement curved tracks **66** using the cable track **66** system **10**, which would allow the tracks **66** to turn corners or be installed in a circular fashion in a large room. Track **66** junctions may be used to connect multiple tracks **66** together as previously described. The supports **72** for the tracks **66** may simply snap or clamp to the cable to provide the proper spacing and support to the cable and RF power transmitters **14** and RF power antennas **50**. The RF power cable track **66** system **10** may be implemented behind a material for aesthetic purposes such as, but not limited to, a wall, ceiling, or drop ceiling.

[**0109**] An RF power transmitter **14** has been designed and constructed to meet the requirements of the track **66** system **10**. The adjustable RF power transmitter **14** is capable of transmitting 0.25 W to 20 W of power as a continuous-wave (CW) or as a pulsed-wave (PW). The transmitter **14** has outside dimensions of 1.5×1.5×4.775 inches. The RF power transmitting antenna **50** at 915 MHz may be implemented with a half-wave dipole that has a length of 6 inches and a diameter of 0.1 inches.

[**0110**] It should be noted that the RF power transmitters **14** described herein may contain communication circuitry and a communication antenna **50** in order to obtain operational information such as, but not limited to, timing, transmitted power, transmission algorithm, frequency, antenna **50** characteristics, or any other information from other RF power transmitters **14**. Additionally, the RF power transmitters **14** may contain a power sensor and antenna **50** for measuring the amount of power transmitted by other RF power transmitters **14** in order to obtain information such as, but not limited to, timing, transmitted power, transmission algorithm, frequency, antenna **50** characteristics, or any other information from other RF power transmitters **14**.

[**0111**] It should be noted that the RF power transmitters **14** described herein may be implemented as a single RF power transmitter **14** or as part of an RF power network where the coverage area **38** of each RF power transmitter **14** may or may not overlap.

[**0112**] Numerous examples have been given herein that describe the physical size of the RF power transmitter **14** and RF power transmitting antenna **50** which may be dependent on one or more of several factors including, but not limited to, transmitted RF power, RF power transmitting antenna **50** gain, the frequency(ies) of the RF power transmitter **14**, the required RF power coverage area **38**, heat sink **54** size, amount of air movement by the fan **56** or by the environment, ambient temperature, and the type of operational power available for the RF power transmitter **14**. These factors may be adjusted or modified to obtain the desired physical size needed in order to implement the RF power transmitter **14** in a practical application such as, but not limited to, using an RF power transmitter **14** plugged directly into a computer **58** to supply RF power to an RF power harvesting device **12** that has been installed into a cellular phone, or using an RF power network to provide an RF power coverage area **38** that covers an office.

[**0113**] The coverage areas **38** and range of the RF transmitters **14** described herein may be dependent on one or more of numerous factors including, but not limited to, transmitted RF power, RF power transmitting antenna **50** gain, the frequency(ies) of the RF power transmitter **14**, the type and amount of operational power available for the RF power transmitter **14**, and the maximum amount of RF power needed to operate the RF power harvesting device(s) **12**. These factors may be adjusted or modified to obtain the desired coverage area **38** needed in order to implement the RF power transmitting and RF power harvesting system **10**.

[**0114**] It should be noted that the operational power for an RF power transmitter **14** and/or RF power network described in the invention herein may be derived from numerous AC or DC sources including, but not limited to, an AC power network, AC power grid **16**, AC power main, DC power network, DC power grid **30**, DC power main, telephone lines or jacks, Ethernet cable or jacks, cable network, or any other AC or DC source. The wiring for these sources may include, but is not limited to, building wire (**10-2, 10-3, 12-2, 12-3, 14-2, 14-3**), telephone wire, CAT-3, CAT-5, CAT-6, coaxial cable, or any other wiring or cable. The way to connect to these wires or to a device may include, but is not limited to, a 2-prong plug **82**, 3-prong plug **82**, DC power plug **82**, vehicle cigarette lighter or power receptacle, RJ-45 connector, RJ-11 connector, F-type connector, screw-on plug **82** or connector, SMA connector, BNC connector, N-type connector, other coaxial connectors, USB connector, mini-USB connector, Firewire connector, product specific connectors, specialized connectors or any other type of connector, plug **82**, or receptacle.

[**0115**] It will be understood by those skilled in the art that while the foregoing description sets forth in detail preferred embodiments of the present invention, modifications, additions, and changes might be made thereto without departing from the spirit and scope of the invention.

The invention claimed is:

1. A power transmission system for wirelessly powering a power harvesting device comprising:

at least one RF power transmitter; and

an AC power grid to which the transmitter is electrically connected.

2. A system as described in claim 1 wherein the power grid has an outlet.

3. A system as described in claim 2 wherein the transmitter has a cord which plugs into the outlet.

4. A system as described in claim 2 wherein the transmitter plugs directly into the outlet.

5. A system as described in claim 2 wherein the power grid has a light.

6. A system as described in claim 5 wherein the power grid has a light switch to turn on the light.

7. A system as described in claim 1 wherein the grid includes in wall wiring.

8. A system as described in claim 7 wherein the transmitter is integrated with the outlet.

9. A system as described in claim 2 wherein the grid has a lighting fixture and the transmitter contacts the fixture.

10. A system as described in claim 5 wherein the grid has a lighting fixture and one or the other of the light and the transmitter contact the fixture.

11. A system as described in claim 1 wherein the grid includes a utility pole to which the transmitter is in contact.

12. A system as described in claim 1 wherein the grid includes a junction box to which transmitter is in contact.

13. A system as described in claim 1 wherein the transmitter includes an AC to DC converter that can convert the AC power obtained from the grid to a usable DC voltage or current.

14. A power transmission system for wirelessly powering a power harvesting device comprising:

at least one RF power transmitter; and

a DC power grid to which the transmitter is electrically connected.

15. A system as described in claim 14 wherein the transmitter is disposed in a vehicle.

16. A system as described in claim 15 wherein the transmitter provides a coverage area over the cabin of the vehicle.

17. A system as described in claim 16 wherein the transmitter is in contact with the dash, trunk, cabin, ceiling, or engine compartment of the vehicle.

18. An adjustable RF power transmitter for powering wirelessly an RF power harvesting device comprising:

a housing having outer dimensions no greater than 3"×3" by 8 inches;

a power input;

a frequency generator in communication with the power input;

an amplifier in communication with the frequency generator;

a controller connected with the frequency generator; and

an antenna connected to the amplifier.

19. A transmitter as described in claim 18 including a circuit board on which the power input, the frequency generator and the amplifier are disposed.

20. A transmitter as described in claim 19 including a heat sink in contact with the circuit board.

21. A transmitter as described in claim 20 including a fan disposed adjacent the circuit board.

22. A power transmission system for wirelessly powering an RF power harvesting device comprising:

a computer;

an antenna;

an RF transmitter in communication with the antenna and the computer; and

a power supply in electrical communication with the RF transmitter and the computer.

23. A system as described in claim 22 wherein the RF transmitter is disposed in the computer.

24. A system as described in claim 22 wherein the computer has a power port and the transmitter is plugged into the power port.

25. A system as described in claim 24 wherein the power port is a USB port.

26. A system as described in claim 22 wherein the antenna is integrated with the transmitter.

27. A system as described in claim 22 including a display, and the antenna is in contact with the display.

28. An apparatus for wirelessly powering a power harvesting device comprising:

at least one RF power transmitter; and

a lighting fixture to which the transmitter is connected and from which the transmitter receives power.

29. An apparatus as described in claim 28 wherein the lighting fixture is a fluorescent lighting fixture.

30. An apparatus as described in claim 28 wherein the lighting fixture is an incandescent lighting fixture.

31. An apparatus as described in claim 28 wherein the lighting fixture is an LED lighting fixture.

32. An apparatus as described in claim 28 including a light source in electrical communication with the lighting fixture.

33. A power transmission system for wirelessly powering a power harvesting device comprising:

at least one RF power transmitter; and

a track supplying power to which the transmitter is electrically connected.

34. A system as described in claim 33 wherein there are at least two power transmitters.

35. A system as described in claim 34 including at least two lights electrically connected to the track.

36. A system as described in claim 35 wherein the track includes a first conductor and a second conductor.

37. A system as described in claim 36 wherein the track includes a support attached to a wall or ceiling.

38. A power transmission system for wirelessly powering a power harvesting device comprising:

at least one RF power transmitter; and

a battery charging unit to which the transmitter is electrically connected.

39. A power transmission system for wirelessly powering a power harvesting device comprising:

at least one RF power transmitter; and

at least one rechargeable battery to which the transmitter is electrically connected.

40. A system as described in claim 39 including a second RF power transmitter which transmits power to the power harvesting device electronically connected to the battery.

41. A system as described in claim 40 including a valve sensor powered by a power harvesting device.

42. A method for wirelessly powering a power harvesting device comprising the steps of:

electrically connecting at least one RF power transmitter to an AC power grid; and

transmitting power with the RF power transmitter.

43. A method for wirelessly powering a power harvesting device comprising the steps of:

electrically connecting at least one RF power transmitter to a DC power grid; and

transmitting power with the RF power transmitter.

44. A method for wirelessly powering a power harvesting device comprising the steps of:

electrically connecting a power supply with an RF transmitter and a computer; and

transmitting power with the RF power transmitter.

45. A method for wirelessly powering a power harvesting device comprising the steps of:

electrically connecting at least one RF power transmitter with a lighting fixture to which the transmitter is in contact with and from which the transmitter receives power; and

transmitting power with the RF power transmitter.

46. A method for wirelessly powering a power harvesting device comprising the steps of:

electrically connecting at least one RF power transmitter to a battery charging unit; and

transmitting power with the RF power transmitter.

47. A power transmission system for wirelessly powering a power harvesting device comprising:

at least one RF power transmitter; and

means for providing power to which the transmitter is electrically connected.

48. An apparatus for wirelessly powering a power harvesting device from a DC power outlet of a vehicle comprising:

an RF power transmitter; and

a power plug to which the transmitter is attached and electrically connected that plugs into the DC power outlet.

49. A power transmission system for wirelessly powering an RF power harvesting device comprising:

an antenna;

an RF transmitter in communication with the antenna; and

a connector in communication with the RF transmitter and configured to be placed in communication with a device.

50. A system as described in claim 49, wherein the device is a computer.

51. A system as described in claim 49, wherein the connector is a USB connector.

52. An apparatus for wirelessly powering a power harvesting device from an AC power grid having an AC power outlet comprising:

an RF power transmitter; and

a power plug to which the transmitter is electrically connected that electrically connects with the AC power outlet.

53. An apparatus for wirelessly powering a power harvesting device from a DC power outlet of a DC grid comprising:

an RF power transmitter; and

a power plug to which the transmitter is electrically connected that electrically connects with the DC power outlet.

54. An apparatus for wirelessly powering a power harvesting device from a computer having an antenna and a power supply comprising:

an RF power transmitter; and

a power plug to which the transmitter is electrically connected that electrically connects with the computer.

55. An apparatus for wirelessly powering a power harvesting device from a light fixture comprising:

an RF power transmitter; and

an electrical interface to which the transmitter is electrically connected that electrically connects with the light fixture.

56. An apparatus for wirelessly powering a power harvesting device from a track having at least one light comprising:

an RF power transmitter; and

an electrical interface to which the transmitter is electrically connected that electrically connects with the track.

57. An apparatus for wirelessly powering a power harvesting device from a battery charging unit comprising:

an RF power transmitter; and

an electrical interface to which the transmitter is electrically connected that electrically connects with the battery charging unit.

(57) **ABSTRACT**

Methods and systems for vector combining power amplification are disclosed herein. In one embodiment, a plurality of signals are individually amplified, then summed to form a desired time-varying complex envelope signal. Phase and/or frequency characteristics of one or more of the signals are controlled to provide the desired phase, frequency, and/or amplitude characteristics of the desired time-varying complex envelope signal. In another embodiment, a time-varying complex envelope signal is decomposed into a plurality of constant envelope constituent signals. The constituent signals are amplified equally or substantially equally, and then summed to construct an amplified version of the original time-varying envelope signal. Embodiments also perform frequency up-conversion.

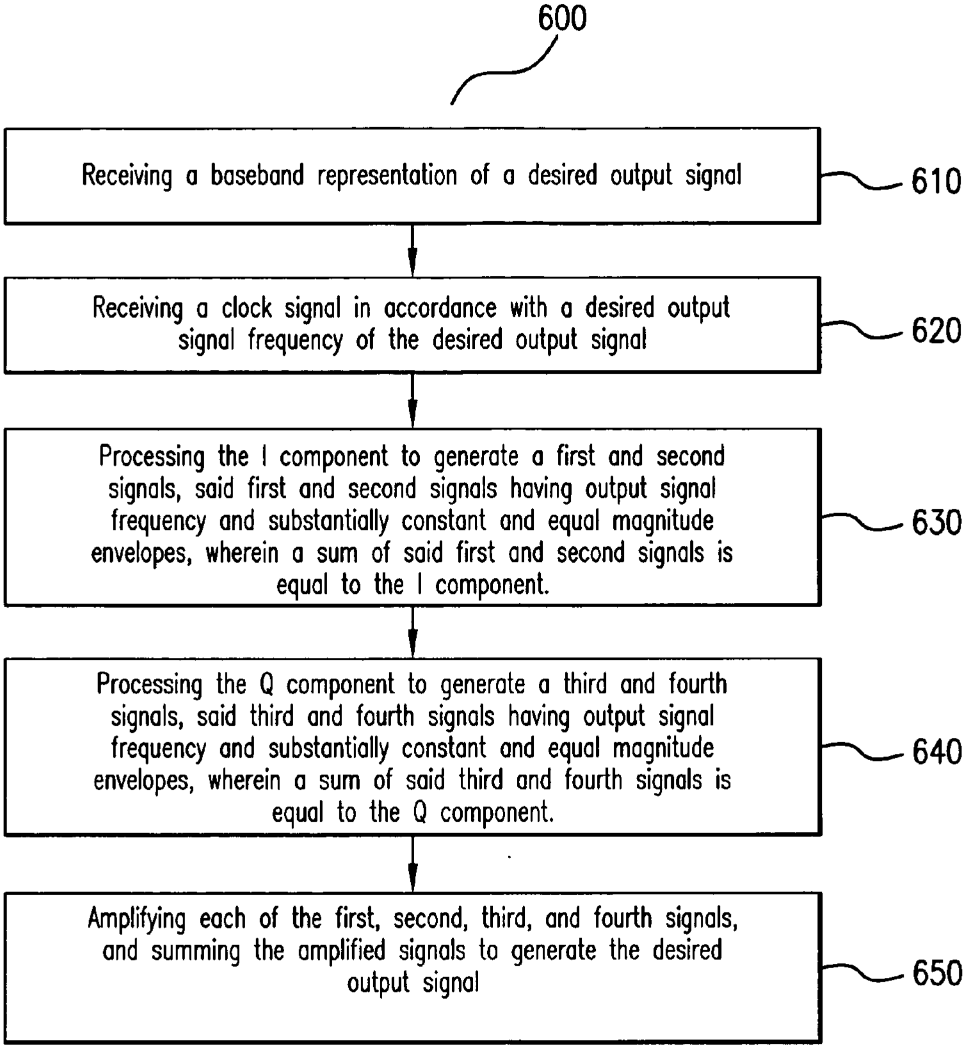
FIG.5



Receiving a baseband representation of a desired output signal

Receiving a clock signal in accordance with a desired output signal frequency of the desired output signal

Processing the I component to generate a first and second signals, said first and second signals having output signal frequency and substantially constant and equal magnitude envelopes, wherein a sum of said first and second signals is equal to the I component.

Processing the Q component to generate a third and fourth signals, said third and fourth signals having output signal frequency and substantially constant and equal magnitude envelopes, wherein a sum of said third and fourth signals is equal to the Q component.

Amplifying each of the first, second, third, and fourth signals, and summing the amplified signals to generate the desired output signal

SYSTEMS AND METHODS OF RF TOWER TRANSMISSION, MODULATION, AND AMPLIFICATION, INCLUDING EMBODIMENTS FOR COMPENSATING FOR WAVEFORM DISTORTION

CROSS-REFERENCE TO RELATED APPLICATIONS

[0001] The present application claims the benefit of U.S. Provisional Patent Application No. 60/794,121 filed on Apr. 24, 2006, U.S. Provisional Patent Application No. 60/797,653 filed on May 5, 2006, and U.S. Provisional Patent Application No. 60/798,750 filed on May 9, 2006, all of which are incorporated herein by reference in their entireties.

BACKGROUND OF THE INVENTION

[0002] 1. Field of the Invention

[0003] The present invention relates generally to RF power transmission, modulation, and amplification. More particularly, the invention relates to methods and systems for vector combining power amplification.

[0004] 2. Background Art

[0005] In power amplifiers, a complex tradeoff typically exists between linearity and power efficiency.

[0006] Linearity is determined by a power amplifier's operating range on a characteristic curve that relates its input to output variables—the more linear the operating range the more linear the power amplifier is said to be. Linearity is a desired characteristic of a power amplifier. In one aspect, for example, it is desired that a power amplifier uniformly amplifies signals of varying amplitude, and/or phase and/or frequency. Accordingly, linearity is an important determiner of the output signal quality of a power amplifier.

[0007] Power efficiency can be calculated using the relationship of the total power delivered to a load divided by the total power supplied to the amplifier. For an ideal amplifier, power efficiency is 100%. Typically, power amplifiers are divided into classes which determine the amplifier's maximum theoretical power efficiency. Power efficiency is clearly a desired characteristic of a power amplifier—particularly, in wireless communication systems where power consumption is significantly dominated by the power amplifier.

[0008] Unfortunately, the traditional tradeoff between linearity and efficiency in power amplifiers is such that the more linear a power amplifier is the less power efficient it is. For example, the most linear amplifier is biased for class A operation, which is the least efficient class of amplifiers. On the other hand, higher class amplifiers such as class B,C,D, E, etc, are more power efficient, but are considerably nonlinear which can result in spectrally distorted output signals.

[0009] The tradeoff described above is further accentuated by typical wireless communication signals. Wireless communication signals, such as OFDM, CDMA, and W-CDMA for example, are generally characterized by their peak-to-average power ratios. The larger the signal's peak to average ratio the more non-linear distortion will be produced when non-linear amplifiers are employed.

[0010] Outphasing amplification techniques have been proposed for RF amplifier designs. In several aspects, however, existing outphasing techniques are deficient in satisfying complex signal amplification requirements, particularly as defined by wireless communication standards, for example.

[0011] In one aspect, existing outphasing techniques employ an isolating and/or a combining element when combining constant envelope constituents of a desired output signal. For example, it is commonly the case that a power combiner is used to combine the constituent signals. This combining approach, however, typically results in a degradation of output signal power due to insertion loss and limited bandwidth, and, correspondingly, a decrease in power efficiency.

[0012] In another aspect, the typically large size of combining elements precludes having them in monolithic amplifier designs.

[0013] What is needed therefore are power amplification methods and systems that solve the deficiencies of existing power amplifying techniques while maximizing power efficiency and minimizing non-linear distortion. Further, power amplification methods and systems that can be implemented without the limitations of traditional power combining circuitry and techniques are needed.

BRIEF SUMMARY OF THE INVENTION

[0014] Embodiments for vector combining power amplification are disclosed herein.

[0015] In one embodiment, a plurality of substantially constant envelope signals are individually amplified, then combined to form a desired time-varying complex envelope signal. Phase and/or frequency characteristics of one or more of the signals are controlled to provide the desired phase, frequency, and/or amplitude characteristics of the desired time-varying complex envelope signal.

[0016] In another embodiment, a time-varying complex envelope signal is decomposed into a plurality of substantially constant envelope constituent signals. The constituent signals are amplified, and then re-combined to construct an amplified version of the original time-varying envelope signal.

[0017] Embodiments of the invention can be practiced with modulated carrier signals and with baseband information and clock signals. Embodiments of the invention also achieve frequency up-conversion. Accordingly, embodiments of the invention represent integrated solutions for frequency up-conversion, amplification, and modulation.

[0018] Embodiments of the invention can be implemented with analog and/or digital controls. The invention can be implemented with analog components or with a combination of analog components and digital components. In the latter embodiment, digital signal processing can be implemented in an existing baseband processor for added cost savings.

[0019] Additional features and advantages of the invention will be set forth in the description that follows. Yet further features and advantages will be apparent to a person skilled in the art based on the description set forth herein or may be learned by practice of the invention. The advantages of the invention will be realized and attained by the structure and methods particularly pointed out in the written description and claims hereof as well as the appended drawings.

[0020] It is to be understood that both the foregoing summary and the following detailed description are exemplary and explanatory and are intended to provide further explanation of embodiments of the invention as claimed.

BRIEF DESCRIPTION OF THE FIGURES

[0021] Embodiments of the present invention will be described with reference to the accompanying drawings, wherein generally like reference numbers indicate identical or functionally similar elements. Also, generally, the left-most digit(s) of the reference numbers identify the drawings in which the associated elements are first introduced.

[0022] FIG. **1**A is an example that illustrates the generation of an exemplary time-varying complex envelope signal.

[0023] FIG. **1**B is another example that illustrates the generation of an exemplary time-varying complex envelope signal.

[0024] FIG. **1**C is an example that illustrates the generation of an exemplary time-varying complex envelope signal from the sum of two or more constant envelope signals.

[0025] FIG. **1**D illustrates the power amplification of an example time-varying complex envelope signal according to an embodiment of the present invention.

[0026] FIG. **1**E is a block diagram that illustrates a vector power amplification embodiment of the present invention.

[0027] FIG. **1** illustrates a phasor representation of a signal.

[0028] FIG. **2** illustrates a phasor representation of a time-varying complex envelope signal.

[0029] FIGS. **3**A-**3**C illustrate an example modulation to generate a time-varying complex envelope signal.

[0030] FIG. **3**D is an example that illustrates constant envelope decomposition of a time-varying envelope signal.

[0031] FIG. **4** is a phasor diagram that illustrates a Cartesian 4-Branch Vector Power Amplification (VPA) method of an embodiment of the present invention.

[0032] FIG. **5** is a block diagram that illustrates an exemplary embodiment of the Cartesian 4-Branch VPA method.

[0033] FIG. **6** is a process flowchart embodiment for power amplification according to the Cartesian 4-Branch VPA method.

[0034] FIG. **7**A is a block diagram that illustrates an exemplary embodiment of a vector power amplifier for implementing the Cartesian 4-Branch VPA method.

[0035] FIG. **7**B is a block diagram that illustrates another exemplary embodiment of a vector power amplifier for implementing the Cartesian 4-Branch VPA method.

[0036] FIG. **8**A is a block diagram that illustrates another exemplary embodiment of a vector power amplifier according to the Cartesian 4-Branch VPA method.

[0037] FIG. **8**B is a block diagram that illustrates another exemplary embodiment of a vector power amplifier according to the Cartesian 4-Branch VPA method.

[0038] FIG. **8**C is a block diagram that illustrates another exemplary embodiment of a vector power amplifier according to the Cartesian 4-Branch VPA method.

[0039] FIG. **8**D is a block diagram that illustrates another exemplary embodiment of a vector power amplifier according to the Cartesian 4-Branch VPA method.

[0040] FIGS. **9**A-**9**B are phasor diagrams that illustrate a Cartesian-Polar-Cartesian-Polar (CPCP) 2-Branch Vector Power Amplification (VPA) method of an embodiment of the present invention.

1. Introduction

[0159] Methods, apparatuses and systems for vector combining power amplification are disclosed herein.

[0160] Vector combining power amplification is an approach for optimizing linearity and power efficiency simultaneously. Generally speaking, and referring to flowchart **502** in FIG. **50**, in step **504** a time-varying complex envelope input signal, with varying amplitude and phase, is decomposed into constant envelope constituent signals. In step **506**, the constant envelope constituent signals are amplified, and then in step **508** summed to generate an amplified version of the input complex envelope signal. Since substantially constant envelope signals may be amplified with minimal concern for non-linear distortion, the result of summing the constant envelope signals suffers minimal non-linear distortion while providing optimum efficiency.

[0161] Accordingly, vector, combining power amplification allows for non-linear power amplifiers to be used to efficiently amplify complex signals whilst maintaining minimal non-linear distortion levels.

[0162] For purposes of convenience, and not limitation, methods and systems of the present invention are sometimes referred to herein as vector power amplification (VPA) methods and systems.

[0163] A high-level description of VPA methods and systems according to embodiments of the present invention is now provided. For the purpose of clarity, certain terms are first defined below. The definitions described in this section are provided for convenience purposes only, and are not limiting. The meaning of these terms will be apparent to persons skilled in the art(s) based on the entirety of the teachings provided herein. These terms may be discussed throughout the specification with additional detail.

[0164] The term signal envelope, when used herein, refers to an amplitude boundary within which a signal is contained as it fluctuates in the time domain. Quadrature-modulated signals can be described by $r(t)=i(t)\cdot\cos(\omega c\cdot t)+q(t)\cdot\sin(\omega\cdot t)$ where i(t) and q(t) represent in-phase and quadrature signals with the signal envelope e(t), being equal to $e(t)=\sqrt{i(t)^2+q(t)^2}$ and the phase angle associated with r(t) is related to arctan (q(t)/i(t)).

[0165] The term constant envelope signal, when used herein, refers to in-phase and quadrature signals where $e(t)=\sqrt{i(t)^2+q(t)^2}$, with e(t) having a relatively or substantially constant value.

[0166] The term time-varying envelope signal, when used herein, refers to a signal having a time-varying signal envelope. A time-varying envelope signal can be described in terms of in-phase and quadrature signals as $e(t)=\sqrt{i(t)^2+q(t)^2}$, with e(t) having a time-varying value.

[0167] The term phase shifting, when used herein, refers to delaying or advancing the phase component of a time-varying or constant envelope signal relative to a reference phase.

1.1) Example Generation of Complex Envelope Time-Varying Input Signals

[0168] FIGS. **1**A and **1**B are examples that illustrate the generation of time-varying envelope and phase complex input signals. In FIG. **1**A, time-varying envelope carrier signals **104** and **106** are input into phase controller **110**. Phase controller **110** manipulates the phase components of signals **104** and **106**. In other words, phase controller **110** may phase shift signals **104** and **106**. Resulting signals **108** and **112**, accordingly, may be phased shifted relative to signals **104** and **106**. In the example of FIG. **1**A, phase controller **110** causes a phase reversal (180 degree phase shift) in signals **104** and **106** at time instant to, as can be seen from signals **108** and **112**. Signals **108** and **112** represent time-varying complex carrier signals. Signals **108** and **112** have both time-varying envelopes and phase components. When summed, signals **108** and **112** result in signal **114**. Signal **114** also represents a time-varying complex signal. Signal **114** may be an example input signal into VPA embodiments of the present invention (for example, an example input into step **504** of FIG. **50**).

[0169] Time-varying complex signals may also be generated as illustrated in FIG. **1**B. In FIG. **1**B, signals **116** and **118** represent baseband signals. For example, signals **116** and **118** may be in-phase (I) and quadrature (Q) baseband components of a signal. In the example of FIG. **1**B, signals **116** and **118** undergo a zero crossing as they transition from +1 to −1. Signals **116** and **118** are multiplied by signal **120** or signal **120** phase shifted by 90 degrees. Signal **116** is multiplied by a 0 degree shifted version of signal **120**. Signal **118** is multiplied by a 90 degree shifted version of signal **120**. Resulting signals **122** and **124** represent time-varying complex carrier signals. Note that signals **122** and **124** have envelopes that vary according to the time-varying amplitudes of signals **116** and **118**. Further, signals **122** and **124** both undergo phase reversals at the zero crossings of signals **116** and **118**. Signals **122** and **124** are summed to result in signal **126**. Signal **126** represents a time-varying complex signal. Signal **126** may represent an example input signal into VPA embodiments of the present invention. Additionally, signals **116** and **118** may represent example input signals into VPA embodiments of the present invention.

1.2) Example Generation of Time-Varying Complex Envelope Signals from Constant Envelope Signals

[0170] The description in this section generally relates to the operation of step **508** in FIG. **50**. FIG. **1**C illustrates three examples for the generation of time-varying complex signals from the sum of two or more substantially constant envelope signals. A person skilled in the art will appreciate, however, based on the teachings provided herein that the concepts illustrated in the examples of FIG. **1**C can be similarly extended to the case of more than two constant envelope signals.

[0171] In example **1** of FIG. **1**C, constant envelope signals **132** and **134** are input into phase controller **130**. Phase controller **130** manipulates phase components of signals **132** and **134** to generate signals **136** and **138**, respectively. Signals **136** and **138** represent substantially constant envelope signals, and are summed to generate signal **140**. The phasor representation in FIG. **1**C, associated with example 1 illustrates signals **136** and **138** as phasors P_{136} and P_{138}, respectively. Signal **140** is illustrated as phasor P_{140}. In example 1, P_{136} and P_{138} are symmetrically phase shifted by an angle ϕ_1 relative to a reference signal assumed to be aligned with the real axis of the phasor representation. Correspondingly, time domain signals **136** and **138** are phase shifted in equal amounts but opposite directions relative to the reference signal. Accordingly, P_{140}, which is the sum of P_{136} and P_{138}, is in-phase with the reference signal.

[0172] In example 2 of FIG. **1**C, substantially constant envelope signals **132** and **134** are input into phase controller **130**. Phase controller **130** manipulates phase components of signals **132** and **134** to generate signals **142** and **144**, respectively. Signals **142** and **144** are substantially constant envelope signals, and are summed to generate signal **150**. The phasor representation associated with example 2 illustrates signals **142** and **144** as phasors P_{142} and P_{144}, respectively. Signal **150** is illustrated as phasor P_{150}. In example 2, P_{142} and P_{144} are symmetrically phase shifted relative to a reference signal. Accordingly, similar to P_{140}, P_{150} is also in-phase with the reference signal. P_{142} and P_{144}, however, are phase shifted by an angle whereby $\phi_2 \neq \phi_1$ relative to the reference signal. P_{150}, as a result, has a different magnitude than P_{140} of example 1. In the time domain representation, it is noted that signals **140** and **150** are in-phase but have different amplitudes relative to each other.

[0173] In example 3 of FIG. **1**C, substantially constant envelope signals **132** and **134** are input into phase controller **130**. Phase controller **130** manipulates phase components of signals **132** and **134** to generate signals **146** and **148**, respectively. Signals **146** and **148** are substantially constant envelope signals, and are summed to generate signal **160**. The phasor representation associated with example 3 illustrates signals **146** and **148** as phasors P_{146} and P_{148}, respectively. Signal **160** is illustrated as phasor P_{160}. In example 3, P_{146} is phased shifted by an angle ϕ_3 relative to the reference signal. P_{148} is phase shifted by an angle ϕ_4 relative to the reference signal. ϕ_3 and ϕ_4 may or may not be equal. Accordingly, P_{160}, which is the sum of P_{146} and P_{148}, is no longer in-phase with the reference signal. P_{160} is phased shifted by an angle Θ relative to the reference signal. Similarly, P_{160} is phase shifted by Θ relative to P_{140} and P_{150} of examples 1 and 2. P_{160} may also vary in amplitude relative to P_{140} as illustrated in example 3.

[0174] In summary, the examples of FIG. **1**C demonstrate that a time-varying amplitude signal can be obtained by the sum of two or more substantially constant envelope signals (Example 1). Further, the time-varying signal can have amplitude changes but no phase changes imparted thereon by equally shifting in opposite directions the two or more substantially constant envelope signals (Example 2). Equally shifting in the same direction the two or more constant envelope constituents of the signal, phase changes but no amplitude changes can be imparted on the time-varying signal. Any time-varying amplitude and phase signal can be generated using two or more substantially constant envelope signals (Example 3).

[0175] It is noted that signals in the examples of FIG. **1**C are shown as sinusoidal waveforms for purpose of illustration only. A person skilled in the art will appreciate based on the teachings herein that other types of waveforms may also have been used. It should also be noted that the examples of FIG. **1**C are provided herein for the purpose of illustration only, and may or may not correspond to a particular embodiment of the present invention.

1.3) Vector Power Amplification Overview

[0176] A high-level overview of vector power amplification is now provided. FIG. **1**D illustrates the power amplification of an exemplary time-varying complex input signal **172**. Signals **114** and **126** as illustrated in FIGS. **1**A and **1**B may be examples of signal **172**. Further, signal **172** may be generated by or comprised of two or more constituent signals such as **104** and **106** (FIG. **1**A), **108** and **112** (FIG. **1**A), **116** and **118** (FIG. **1**B), and **122** and **124** (FIG. **1**B).

[0177] In the example of FIG. **1**D, VPA **170** represents a VPA system embodiment according to the present invention. VPA **170** amplifies signal **172** to generate amplified output signal **178**. Output signal **178** is amplified efficiently with minimal distortion.

[0178] In the example of FIG. **1**D, signals **172** and **178** represent voltage signals $V_{in}(t)$ and $V_{olt}(t)$, respectively. At any time instant, in the example of FIG. **1**D, $V_{in}(t)$ and $V_{olt}(t)$ are related such that $V_{olt}(t)=Kev_{in}(tat')$, where K is a scale factor and t' represents a time delay that may be present in the VPA system. For power implication,

$$\frac{V_{out}^2(t)}{Z_{out}} > \frac{V_{in}^2(t)}{Z_{in}},$$

where output signal **178** is a power amplified version of input signal **172**.

[0179] Linear (or substantially linear) power amplification of time-varying complex signals, as illustrated in FIG. **1**D, is achieved according to embodiments of the present as shown in FIG. **1**E.

[0180] FIG. **1**E is an example block diagram that conceptually illustrates a vector power amplification embodiment according to embodiments of the present invention. In FIG. **1**E, input signal **172** represents a time-varying complex signal. For example, input signal **172** may be generated as illustrated in FIGS. **1**A and **1**B. In embodiments, signal **172** may be a digital or an analog signal. Further, signal **172** may be a baseband or a carrier-based signal.

[0181] Referring to FIG. **1**E, according to embodiments of the present invention, input signal **172** or equivalents thereof are input into VPA **182**. In the embodiment of FIG. **1**E, VPA **182** includes a state machine **184** and analog circuitry **186**. State machine **184** may include digital and/or analog components. Analog circuitry **186** includes analog components. VPA **182** processes input signal **172** to generate two or more signals **188**-{**1**, . . . , n}, as illustrated in FIG. **1**E. As described with respect to signals **136**, **138**, **142**, **144**, and **146**, **148**, in FIG. **1**C, signals **188**-{**1**, . . . , n} may or may not be phase shifted relative to each other over different periods of time. Further, VPA **182** generates signals **188**-{**1**, . . . , n} such that a sum of signals **188**-{**1**, . . . , n} results in signal **194** which, in certain embodiments, can be an amplified version of signal **172**.

[0182] Still referring to FIG. **1**E, signals **188**-{**1**, . . . , n} are substantially constant envelope signals. Accordingly, the description in the prior paragraph corresponds to step **504** in FIG. **50**.

[0183] In the example of FIG. **1**E, generally corresponding to step **506** in FIG. **50**, constant envelope signals **188**-{**1**, . . . , n} are each independently amplified by a corresponding power amplifier (PA) **190**-{**1**, . . . , n} to generate amplified signals **192**-{**1**, . . . , n}. In embodiments, PAs **190**-{**1**, . . . , n} amplify substantially equally respective constant envelope signals **188**-{**1**, . . . , n}. Amplified signals **192**-{**1**, . . . , n} are substantially constant envelope signals, and in step **508** are summed to generate output signal **194**. Note that output signal **194** can be a linearly (or substantially linearly) amplified version of input signal **172**. Output signal **194** may also be a frequency-upconverted version of input signal **172**, as described herein.

2. General Mathematical Overview

2.1) Phasor Signal Representation

[0184] FIG. **1** illustrates a phasor representation $\vec{R}$ **102** of a signal r(t). A phasor representation of a signal is explicitly representative of the magnitude of the signal's envelope and of the signal's phase shift relative to a reference signal. In this document, for purposes of convenience, and not limitation, the reference signal is defined as being aligned with the real (Re) axis of the orthogonal space of the phasor representation. The invention is not, however, limited to this embodiment. The frequency information of the signal is implicit in the representation, and is given by the frequency of the reference signal. For example, referring to FIG. **1**, and assuming that the real axis corresponds to a $\cos(\omega t)$ reference signal, phasor $\vec{R}$ would translate to the function $r(t)=R(t)\cos(\omega t+\phi(t))$, where R is the magnitude of $\vec{R}$.

[0185] Still referring to FIG. **1**, it is noted that phasor $\vec{R}$ can be decomposed into a real part phasor $\vec{I}$ and an imaginary part phasor $\vec{Q}$. $\vec{I}$ and $\vec{Q}$ are said to be the in-phase and quadrature phasor components of $\vec{R}$ with respect to the reference signal. It is further noted that the signals that correspond to $\vec{I}$ and $\vec{Q}$ are related to r(t) as $I(t)=R(t)\cdot\cos(\phi(t))$ and $Q(t)=R(t)\cdot\sin(\phi(t))$, respectively. In the time domain, signal r(t) can also be written in terms of its in-phase and quadrature components as follows:

$$r(t)=I(t)\cdot\cos(\omega t)+Q(t)\cdot\sin(\omega t)=R(t)\cdot\cos(\phi(t))\cdot\cos(\omega t)+R(t)\cdot\sin(\phi(t))\cdot\sin(\omega t) \tag{1}$$

[0186] Note that, in the example of FIG. **1**, R(t) is illustrated at a particular instant of time.

2.2) Time-Varying Complex Envelope Signals

[0187] FIG. **2** illustrates a phasor representation of a signal r(t) at two different instants of time t**1** and t**2**. It is noted that the magnitude of the phasor, which represents the magnitude of the signal's envelope, as well as its relative phase shift both vary from time t**1** to time t**2**. In FIG. **2**, this is illustrated by the varying magnitude of phasors $\vec{R_1}$ and $\vec{R_2}$ and their corresponding phase shift angles ϕ_1 and ϕ_2. Signal r(t), accordingly, is a time-varying complex envelope signal.

[0188] It is further noted, from FIG. **2**, that the real and imaginary phasor components of signal r(t) are also time-varying in amplitude. Accordingly, their corresponding time domain signals also have time-varying envelopes.

[0189] FIGS. 3A-3C illustrate an example modulation to generate a time-varying complex envelope signal. FIG. 3A illustrates a view of a signal m(t). FIG. 3B illustrates a view of a portion of a carrier signal c(t). FIG. 3C illustrates a signal r(t) that results from the multiplication of signals m(t) and c(t).

[0190] In the example of FIG. 3A, signal m(t) is a time-varying magnitude signal. m(t) further undergoes a zero crossing. Carrier signal c(t), in the example of FIG. 3B, oscillates at some carrier frequency, typically higher than that of signal m(t).

[0191] From FIG. 3C, it can be noted that the resulting signal r(t) has a time-varying envelope. Further, it is noted, from FIG. 3C, that r(t) undergoes a reversal in phase at the moment when the modulating signal m(t) crosses zero. Having both non-constant envelope and phase, r(t) is said to be a time-varying complex envelope signal.

2.3) Constant Envelope Descomposition of Time-Varying Envelope Signals

[0192] Any phasor of time-varying magnitude and phase can be obtained by the sum of two or more constant magnitude phasors having appropriately specified phase shifts relative to a reference phasor.

[0193] FIG. 3D illustrates a view of an example time-varying envelope and phase signal S(t). For ease of illustration, signal S(t) is assumed to be a sinusoidal signal having a maximum envelope magnitude A. FIG. 3D further shows an example of how signal S(t) can be obtained, at any instant of time, by the sum of two constant envelope signals $S_1(t)$ and $S_2(t)$. Generally, $S_1(t)=A_1 \sin(\omega t+\phi_1(t))$ and $S_1(t)=A_2 \sin(\omega+\phi_2(t))$.

[0194] For the purpose of illustration, three views are provided in FIG. 3D that illustrate how by appropriately phasing signals $S_1(t)$ and $S_2(t)$ relative to S(t), signals $S_1(t)$ and $S_2(t)$ can be summed so that $S(t)=K(S_1(t)+S_2(t))$ where K is a constant. In other words, signal S(t) can be decomposed, at any time instant, into two or more signals. From FIG. 3D, over period T_1, $S_1(t)$ and $S_2(t)$ are both in-phase relative to signal S(t), and thus sum to the maximum envelope magnitude A of signal S(t). Over period T_3, however, signals $S_1(t)$ and $S_2(t)$ are 180 degree out-of-phase relative to each other, and thus sum to a minimum envelope magnitude of signal S(t).

[0195] The example of FIG. 3D illustrates the case of sinusoidal signals. A person skilled in the art, however, will understand that any time-varying envelope, which modulates a carrier signal that can be represented by a Fourier series or Fourier transform, can be similarly decomposed into two or more substantially constant envelope signals. Thus, by controlling the phase of a plurality of substantially constant envelope signals, any time-varying complex envelope signal can be generated.

3. Vector Power Amplification Methods and Systems

[0196] Vector power amplification methods and systems according to embodiments of the present invention rely on the ability to decompose any time-varying envelope signal into two or more substantially constant envelope constituent signals or to receive or generate such constituent signals, amplify the constituent signals, and then sum the amplified signals to generate an amplified version of the time-varying complex envelope signal.

[0197] In sections 3.1-3.3, vector power amplification (VPA) embodiments of the present invention are provided, including 4-branch and 2-branch embodiments. In the description, each VPA embodiment is first presented conceptually using a mathematical derivation of underlying concepts of the embodiment. An embodiment of a method of operation of the VPA embodiment is then presented, followed by various system level embodiments of the VPA embodiment.

[0198] Section 3.4 presents various embodiments of control modules according to embodiments of the present invention. Control modules according to embodiments of the present invention may be used to enable certain VPA embodiments of the present invention. In some embodiments, the control modules are intermediary between an input stage of the VPA embodiment and a subsequent vector modulation stage of the VPA embodiment.

[0199] Section 3.5 describes VPA output stage embodiments according to embodiments of the present invention. Output stage embodiments are directed to generating the output signal of a VPA embodiment.

[0200] Section 3.6 is directed to harmonic control according to embodiments of the present invention. Harmonic control may be implemented in certain embodiments of the present invention to manipulate the real and imaginary power in the harmonics of the VPA embodiment, thus increasing the power present in the fundamental frequency at the output.

[0201] Section 3.7 is directed to power control according to embodiments of the present invention. Power control may be implemented in certain embodiments of the present invention in order to satisfy power level requirements of applications where VPA embodiments of the present invention may be employed.

3.1) Cartesian 4-Branch Vector Power Amplifier

[0202] According to one embodiment of the invention, herein called the Cartesian 4-Branch VPA embodiment for ease of illustration and not limitation, a time-varying complex envelope signal is decomposed into 4 substantially constant envelope constituent signals. The constituent signals are equally or substantially equally amplified individually, and then summed to construct an amplified version of the original time-varying complex envelope signal.

[0203] It is noted that 4 branches are employed in this embodiment for purposes of illustration, and not limitation. The scope of the invention covers use of other numbers of branches, and implementation of such variations will be apparent to persons skilled in the art based on the teachings contained herein.

[0204] In one embodiment, a time-varying complex envelope signal is first decomposed into its in-phase and quadrature vector components. In phasor representation, the in-phase and quadrature vector components correspond to the signal's real part and imaginary part phasors, respectively.

[0205] As described above, magnitudes of the in-phase and quadrature vector components of a signal vary proportionally to the signal's magnitude, and are thus not constant envelope when the signal is a time-varying envelope signal. Accordingly, the 4-Branch VPA embodiment further decomposes each of the in-phase and quadrature vector components of the signal into four substantially constant envelope components, two for the in-phase and two for the quadrature signal components. This concept is illustrated in FIG. **4** using a phasor signal representation.

[0206] In the example of FIG. **4**, phasors $\vec{I_1}$ and $\vec{I_2}$ correspond to the real part phasors of an exemplary time-varying complex envelope signal at two instants of time t**1** and t**2**, respectively. It is noted that phasors $\vec{I_1}$ and $\vec{I_2}$ have different magnitudes.

[0207] Still referring to FIG. **4**, at instant t**1**, phasor $\vec{I_1}$ can be obtained by the sum of upper and lower phasors $\vec{I_{U_1}}$ and $\vec{I_{L_1}}$. Similarly, at instant t**2**, phasor $\vec{I_2}$ can be obtained by the sum of upper and lower phasors $\vec{I_{U_2}}$ and $\vec{I_{L_2}}$. Note that phasors $\vec{I_{U_1}}$ and $\vec{I_{U_2}}$ have equal or substantially equal magnitude. Similarly, phasors $\vec{I_{L_1}}$ and $\vec{I_{L_2}}$ have substantially equal magnitude. Accordingly, the real part phasor of the time-varying envelope signal can be obtained at any time instant by the sum of at least two substantially constant envelope components.

[0208] The phase shifts of phasors $\vec{I_{U_1}}$ and $\vec{I_{L_1}}$ relative to $\vec{I_1}$, as well as the phase shifts of phasors $\vec{I_{U_2}}$ and $\vec{I_{L_2}}$ relative to $\vec{I_2}$ are set according to the desired magnitude of phasors $\vec{I_1}$ and $\vec{I_2}$, respectively. In one case, when the upper and lower phasors are selected to have equal magnitude, the upper and lower phasors are symmetrically shifted in phase relative to the phasor. This is illustrated in the example of FIG. **4**, and corresponds to $\vec{I_{U_1}}$, $\vec{I_{L_1}}$, $\vec{I_{U_2}}$, and $\vec{I_{L_2}}$ all having equal magnitude. In a second case, the phase shift of the upper and lower phasors are substantially symmetrically shifted in phase relative to the phasor. Based on the description herein, anyone skilled in the art will understand that the magnitude and phase shift of the upper and lower phasors do not have to be exactly equal in value

[0209] As an example, it can be further verified that, for the case illustrated in FIG. **4**, the relative phase shifts, illustrated as

$$\frac{\phi_1}{2} \text{ and } \frac{\phi_2}{2}$$

in FIG. **4**, are related to the magnitudes of normalized phasors $\vec{I_1}$ and $\vec{I_2}$ as follows:

$$\frac{\phi_1}{2} = \cot^{-1}\left(\frac{I_1}{2\sqrt{1-\frac{I_1^2}{4}}}\right); \text{ and} \tag{2}$$

$$\frac{\phi_2}{2} = \cot^{-1}\left(\frac{I_2}{2\sqrt{1-\frac{I_2^2}{4}}}\right), \tag{3}$$

[0210] wherein I_1 and I_2 represent the normalized magnitudes of phasors $\vec{I_1}$ and $\vec{I_2}$, respectively, and wherein the domains of I_1 and I_2 are restricted appropriately according to the domain over which equation (2) and (3) are valid. It is noted that equations (2) and (3) are one representation for relating the relative phase shifts to the normalized magnitudes. Other, solutions, equivalent representations, and/or simplified representations of equations (2) and (3) may also be employed. Look up tables relating relative phase shifts to normalized magnitudes may also be used.

[0211] The concept describe above can be similarly applied to the imaginary phasor or the quadrature component part of a signal r(t) as illustrated in FIG. **4**. Accordingly, at any time instant t, imaginary phasor part $\vec{Q}$ of signal r(t) can be obtained by summing upper and lower phasor components $\vec{Q_U}$ and $\vec{Q_L}$ of substantially equal and constant magnitude. In this example, $\vec{Q_U}$ and $\vec{Q_L}$ are symmetrically shifted in phase relative to $\vec{Q}$ by an angle set according to the magnitude of $\vec{Q}$ at time t. The relationship of $\vec{Q_U}$ and $\vec{Q_L}$ to the desired phasor $\vec{Q}$ are related as defined in equations 2 and 3 by substituting Q_1 and Q_2 for I_1 and I_2 respectively.

[0212] It follows from the above discussion that, in phasor representation, any phasor $\vec{R}$ of variable magnitude and phase can be constructed by the sum of four substantially constant magnitude phasor components:

$$\vec{R}=\vec{I_U}+\vec{I_L}+\vec{Q_U}+\vec{Q_L};$$

$$\vec{I_U}+\vec{I_L}=\vec{I};$$

$$\vec{Q_U}+\vec{Q_L}=\vec{Q};$$

$$I_U=I_L=\text{constant};$$

$$Q_U=Q_L=\text{constant}; \tag{4}$$

where I_U, I_L, Q_U, and Q_L represent the magnitudes of phasors $\vec{I_U}$, $\vec{I_L}$, $\vec{Q_U}$, and $\vec{Q_L}$, respectively.

[0213] Correspondingly, in the time domain, a time-varying complex envelope sinusoidal signal $r(t)=R(t)\cos(\omega t+\phi)$ is constructed by the sum of four constant envelope signals as follows:

$$r(t) = I_U(t) + I_L(t) + Q_U(t) + Q_L(t); \tag{5}$$

$$I_U(t) = sgn(\vec{I}) \times I_U\cos\left(\frac{\phi_I}{2}\right)\times\cos(\omega t) + I_U \times \sin\left(\frac{\phi_I}{2}\right)\times\sin(\omega t);$$

$$I_L(t) = sgn(\vec{I}) \times I_L\cos\left(\frac{\phi_I}{2}\right)\times\cos(\omega t) - I_L \times \sin\left(\frac{\phi_I}{2}\right)\times\sin(\omega t);$$

$$Q_U(t) = sgn(\vec{Q}) \times Q_U\cos\left(\frac{\phi_Q}{2}\right)\times\sin(\omega t) + Q_U \times \sin\left(\frac{\phi_Q}{2}\right)\times\cos(\omega t);$$

$$Q_L(t) = sgn(\vec{Q}) \times Q_L\cos\left(\frac{\phi_Q}{2}\right)\times\sin(\omega t) - Q_L \times \sin\left(\frac{\phi_Q}{2}\right)\times\cos(\omega t).$$

where $sgn(\vec{I})=\pm 1$ depending on whether $\vec{I}$ is in-phase or 180° degrees out-of-phase with the positive real axis. Similarly, $sgn(\vec{Q})=\pm 1$ depending on whether $\vec{Q}$ is in-phase or 180° degrees out-of-phase with the imaginary axis.

$$\frac{\phi_I}{2}$$

corresponds to the phase shift of $\vec{I_U}$ and $\vec{I_L}$ relative to the real axis. Similarly,

$$\frac{\phi_Q}{2}$$

corresponds to the phase shift of $\vec{Q}_U$ and $\vec{Q}_L$ relative to the imaginary axis.

$$\frac{\phi_I}{2} \text{ and } \frac{\phi_Q}{2}$$

can be calculated using the equations given in (2) and (3).

[0214] Equations (5) can be further simplified as:

$$r(t) = I_U(t) + I_L(t) + Q_U(t) + Q_L(t); \tag{6}$$

$$I_U(t) = sgn(\vec{I}) \times I_{UX} \times \cos(\omega t) + I_{UY} \times \sin(\omega t);$$

$$I_L(t) = sgn(\vec{I}) \times I_{UX} \times \cos(\omega t) - I_{UY} \times \sin(\omega t);$$

$$Q_U(t) = -Q_{UX} \times \cos(\omega t) + sgn(\vec{Q}) \times Q_{UY} \times \sin(\omega t);$$

$$Q_L(t) = Q_{UY} \times \cos(\omega t) - sgn(\vec{Q}) \times Q_{UY} \times \sin(\omega t).$$

$$I_{UX} = I_U \times \cos\left(\frac{\phi_I}{2}\right) = I_L \times \cos\left(\frac{\phi_I}{2}\right), \text{ where}$$

$$I_{UY} = I_U \times \sin\left(\frac{\phi_I}{2}\right) = I_L \times \sin\left(\frac{\phi_I}{2}\right),$$

$$Q_{UX} = Q_U \times \sin\left(\frac{\phi_Q}{2}\right) = Q_L \times \sin\left(\frac{\phi_Q}{2}\right), \text{ and}$$

$$Q_{UY} = Q_U \times \cos\left(\frac{\phi_Q}{2}\right) = Q_L \times \cos\left(\frac{\phi_Q}{2}\right).$$

[0215] It can be understood by a person skilled in the art that, whereas the time domain representations in equations (5) and (6) have been provided for the case of a sinusoidal waveform, equivalent representations can be developed for non-sinusoidal waveforms using appropriate basis functions. Further, as understood by a person skilled in the art based on the teachings herein, the above-describe two-dimensional decomposition into substantially constant envelope signals can be extended appropriately into a multi-dimensional decomposition.

[0216] FIG. **5** is an example block diagram of the Cartesian 4-Branch VPA embodiment. An output signal r(t) **578** of desired power level and frequency characteristics is generated from baseband in-phase and quadrature components according to the Cartesian 4-Branch VPA embodiment.

[0217] In the example of FIG. **5**, a frequency generator such as a synthesizer **510** generates a reference signal A*cos(ωt) **511** having the same frequency as that of output signal r(t) **578**. It can be understood by a person skilled in the art that the choice of the reference signal is made according to the desired output signal. For example, if the desired frequency of the desired output signal is 2.4 GHz, then the frequency of the reference signal is set to be 2.4 GHz. In this manner, embodiments of the invention achieve frequency up-conversion.

[0218] Referring to FIG. **5**, one or more phase splitters are used to generate signals **521**, **531**, **541**, and **551** based on the reference signal **511**. In the example of FIG. **5**, this is done using phase splitters **512**, **514**, and **516** and by applying 0° phase shifts at each of the phase splitters. A person skilled in the art will appreciate, however, that various techniques may be used for generating signals **521**, **531**, **541**, and **551** of the reference signal **511**. For example, a 1:4 phase splitter may be used to generate the four replicas **521**, **531**, **541**, and **551** in a single step or in the example embodiment of FIG. **5**, signal **511** can be directly coupled to signals **521**, **531**, **541**, **551** Depending on the embodiment, a variety of phase shifts may also be applied to result in the desired signals **521**, **531**, **541**, and **551**.

[0219] Still referring to FIG. **5**, the signals **521**, **531**, **541**, and **551** are each provided to a corresponding vector modulator **520**, **530**, **540**, and **550**, respectively. Vector modulators **520**, **530**, **540**, and **550**, in conjunction with their appropriate input signals, generate four constant envelope constituents of signal r(t) according to the equations provided in (6). In the example embodiment of FIG. **5**, vector modulators **520** and **530** generate the I_U(t) and I_L(t) components, respectively, of signal r(t). Similarly, vector modulators **540** and **550** generate the Q_U(t) and Q_L(t) components, respectively, of signal r(t).

[0220] The actual implementation of each of vector modulators **520**, **530**, **540**, and **550** may vary. It will be understood by a person skilled in the art, for example, that various techniques exist for generating the constant envelope constituents according to the equations in (6).

[0221] In the example embodiment of FIG. **5**, each of vector modulators **520**, **530**, **540**, **550** includes an input phase splitter **522**, **532**, **542**, **552** for phasing the signals **522**, **531**, **541**, **551**. Accordingly, input phase splitters **522**, **532**, **542**, **552** are used to generate an in-phase and a quadrature components or their respective input signals.

[0222] In each vector modulator **520**, **530**, **540**, **550**, the in-phase and quadrature components are multiplied with amplitude information. In FIG. **5**, for example, multiplier **524** multiplies the quadrature component of signal **521** with the quadrature amplitude information I_{UY} of I_U(t). In parallel, multiplier **526** multiplies the in-phase replica signal with the in-phase amplitude information sgn(I)×I_{UX} of I_U(t).

[0223] To generate the I_U(t) constant envelope constituent signals **525** and **527** are summed using phase splitter **528** or alternate summing techniques. The resulting signal **529** corresponds to the IU(t) component of signal r(t).

[0224] In similar fashion as described above, vector modulators **530**, **540**, and **550**, respectively, generate the I_L(t), Q_U(t), and Q_L(t) components of signal r(t). I_L(t), Q_U(t), and Q_L(t), respectively, correspond to signals **539**, **549**, and **559** in FIG. **5**.

[0225] Further, as described above, signals **529**, **539**, **549**, and **559** are characterized by having substantially equal and constant magnitude envelopes. Accordingly, when signals **529**, **539**, **549**, and **559** are input into corresponding power amplifiers (PA) **562**, **564**, **566**, and **568**, corresponding amplified signals **563**, **565**, **567**, and **569** are substantially constant envelope signals.

[0226] Power amplifiers **562**, **564**, **566**, and **568** amplify each of the signals **529**, **539**, **549**, **559**, respectively. In an embodiment, substantially equal power amplification is applied to each of the signals **529**, **539**, **549**, and **559**. In an embodiment, the power amplification level of PAs **562**, **564**, **566**, and **568** is set according to the desired power level of output signal r(t).

[0227] Still referring to FIG. **5**, amplified signals **563** and **565** are summed using summer **572** to generate an amplified version **573** of the in-phase component $\vec{I}$ (t) of signal r(t).

Similarly, amplified signals **567** and **569** are summed using summer **574** to generate an amplified version **575** of the quadrature component $\vec{Q}$ (t) of signal r(t).

[0228] Signals **573** and **575** are summed using summer **576**, as shown in FIG. **5**, with the resulting signal corresponding to desired output signal r(t).

[0229] It must be noted that, in the example of FIG. **5**, summers **572**, **574**, and **576** are being used for the purpose of illustration only. Various techniques may be used to sum amplified signals **563**, **565**, **567**, and **569**. For example, amplified signals **563**, **565**, **567**, and **569** may be summed all in one step to result in signal **578**. In fact, according to various VPA embodiments of the present invention, it suffices that the summing is done after amplification. Certain VPA embodiments of the present invention, as will be further described below, use minimally lossy summing techniques such as direct coupling via wire. Alternatively, certain VPA embodiments use conventional power combining techniques. In other embodiments, as will be further described below, power amplifiers **562**, **564**, **566**, and **568** can be implemented as a multiple-input single-output power amplifier.

[0230] Operation of the Cartesian 4-Branch VPA embodiment shall now be further described with reference to the process flowchart of FIG. **6**. The process begins at step **610**, which includes receiving the baseband representation of the desired output signal. In an embodiment, this involves receiving in-phase (I) and quadrature (Q) components of the desired output signal. In another embodiment, this involves receiving magnitude and phase of the desired output signal. In an embodiment of the Cartesian 4-Branch VPA embodiment, the I and Q are baseband components. In another embodiment, the I and Q are RF components and are down-converted to baseband.

[0231] Step **620** includes receiving a clock signal set according to a desired output signal frequency of the desired output signal. In the example of FIG. **5**, step **620** is achieved by receiving reference signal **511**.

[0232] Step **630** includes processing the I component to generate first and second signals having the output signal frequency. The first and second signals have substantially constant and equal magnitude envelopes and a sum equal to the I component. The first and second signals correspond to the $I_U(t)$ and $I_L(t)$ constant envelope constituents described above. In the example of FIG. **5**, step **630** is achieved by vector modulators **520** and **530**, in conjunction with their appropriate input signals.

[0233] Step **640** includes processing the Q component to generate third and fourth signals having the output signal frequency. The third and fourth signals have substantially constant and equal magnitude envelopes and a sum equal to the Q component. The third and fourth signals correspond to the $Q_U(t)$ and $Q_L(t)$ constant envelope constituents described above. In the example of FIG. **5**, step **630** is achieved by vector modulators **540** and **550**, in conjunction with their appropriate input signals.

[0234] Step **650** includes individually amplifying each of the first, second, third, and fourth signals, and summing the amplified signals to generate the desired output signal. In an embodiment, the amplification of the first, second, third, and fourth signals is substantially equal and according to a desired power level of the desired output signal. In the example of FIG. **5**, step **650** is achieved by power amplifiers **562**, **564**, **566**, and **568** amplifying respective signals **529**, **539**, **549**, and **559**, and by summers **572**, **574**, and **576** summing amplified signals **563**, **565**, **567**, and **569** to generate output signal **578**.

[0235] FIG. **7**A is a block diagram that illustrates an exemplary embodiment of a vector power amplifier **700** implementing the process flowchart **600** of FIG. **6**. In the example of FIG. **7**A, optional components are illustrated with dashed lines. In other embodiments, additional components may be optional.

[0236] Vector power amplifier **700** includes an in-phase (I) branch **703** and a quadrature (Q) branch **705**. Each of the I and Q branches further comprises a first branch and a second branch.

[0237] In-phase (I) information signal **702** is received by an I Data Transfer Function module **710**. In an embodiment, I information signal **702** includes a digital baseband signal. In an embodiment, I Data Transfer Function module **710** samples I information signal **702** according to a sample clock **706**. In another embodiment, I information signal **702** includes an analog baseband signal, which is converted to digital using an analog-to-digital converter (ADC) (not shown in FIG. **7**A) before being input into I Data Transfer Function module **710**. In another embodiment, I information signal **702** includes an analog baseband signal which input in analog form into I Data Transfer Function module **710**, which also includes analog circuitry. In another embodiment, I information signal **702** includes a RF signal which is down-converted to baseband before being input into I Data Transfer Function module **710** using any of the above described embodiments.

[0238] I Data Transfer Function module **710** processes I information signal **702**, and determines in-phase and quadrature amplitude information of at least two constant envelope constituent signals of I information signal **702**. As described above with reference to FIG. **5**, the in-phase and quadrature vector modulator input amplitude information corresponds to $\mathrm{sgn}(I)\times I_{UX}$ and I_{UY}, respectively. The operation of I Data Transfer Function module **710** is further described below in section 3.4.

[0239] I Data Transfer Function module **710** outputs information signals **722** and **724** used to control the in-phase and quadrature amplitude components of vector modulators **760** and **762**. In an embodiment, signals **722** and **724** are digital signals. Accordingly, each of signals **722** and **724** is fed into a corresponding digital-to-analog converter (DAC) **730** and **732**, respectively. The resolution and sample rate of DACs **730** and **732** is selected to achieve the desired I component of the output signal **782**. DACs **730** and **732** are controlled by DAC clock signals **723** and **725**, respectively. DAC clock signals **723** and **725** may be derived from a same clock signal or may be independent.

[0240] In another embodiment, signals **722** and **724** are analog signals, and DACs **730** and **732** are not required.

[0241] In the exemplary embodiment of FIG. **7**A, DACs **730** and **732** convert digital information signals **722** and **724** into corresponding analog signals, and input these analog signals into optional interpolation filters **731** and **733**, respectively. Interpolation filters **731** and **733**, which also serve as anti-aliasing filters, shape the DACs outputs to produce the desired output waveform. Interpolation filters **731** and **733** generate signals **740** and **742**, respectively. Signal **741** represents the inverse of signal **740**. Signals **740**-**742** are input into vector modulators **760** and **762**.

[0242] Vector modulators **760** and **762** multiply signals **740-742** with appropriately phased clock signals to generate constant envelope constituents of I information signal **702**. The clock signals are derived from a channel clock signal **708** having a rate according to a desired output signal frequency. A plurality of phase splitters, such as **750** and **752**, for example, and phasors associated with the vector modulator multipliers may be used to generate the appropriately phased clock signals.

[0243] In the embodiment of FIG. **7**A, for example, vector modulator **760** modulates a 90° shifted channel clock signal with quadrature amplitude information signal **740**. In parallel, vector modulator **760** modulates an in-phase channel clock signal with in-phase amplitude information signal **742**. Vector modulator **760** combines the two modulated signals to generate a first modulated constant envelope constituent **761** of I information signal **702**. Similarly, vector modulator **762** generates a second modulated constant envelope constituent **763** of I information signal **702**, using signals **741** and **742**. Signals **761** and **763** correspond, respectively, to the $I_U(t)$ and $I_L(t)$ constant envelope components described with reference to FIG. **5**.

[0244] In parallel and in similar fashion, the Q branch of vector power amplifier **700** generates at least two constant envelope constituent signals of quadrature (Q) information signal **704**.

[0245] In the embodiment of FIG. **7**A, for example, vector modulator **764** generates a first constant envelope constituent **765** of Q information signal **704**, using signals **744** and **746**. Similarly, vector modulator **766** generates a second constant envelope constituent **767** of Q information signal **704**, using signals **745** and **746**.

[0246] As described above with respect to FIG. **5**, constituent signals **761**, **763**, **765**, and **767** have substantially equal and constant magnitude envelopes. In the exemplary embodiment of FIG. **7**A, signals **761**, **763**, **765**, and **767** are, respectively, input into corresponding power amplifiers (PAs) **770**, **772**, **774**, and **776**. PAs **770**, **772**, **774**, and **776** can be linear or non-linear power amplifiers. In an embodiment, PAs **770**, **772**, **774**, and **776** include switching power amplifiers.

[0247] Circuitry **714** and **716** (herein referred to as "autobias circuitry" for ease of reference, and not limitation) and in this embodiment, control the bias of PAs **770**, **772**, **774**, and **776** according to I and Q information signals **702** and **704**. In the embodiment of FIG. **7**A, autobias circuitry **714** and **716** provide, respectively, bias signals **715** and **717** to PAs **770**, **772** and PAs **774**, **776**. Autobias circuitry **714** and **716** are further described below in section 3.5. Embodiments of PAs **770**, **772**, **774**, and **776** are also discussed below in section 3.5.

[0248] In an embodiment, PAs **770**, **772**, **774**, and **776** apply substantially equal power amplification to respective substantially constant envelope signals **761**, **763**, **765**, and **767**. In other embodiments, PA drivers are additionally employed to provide additional power amplification. In the embodiment of FIG. **7**A, PA drivers **794**, **795**, **796**, and **797** are optionally added between respective vector modulators **760**, **762**, **764** **766** and respective PAs **770**, **772**, **774**, and **776**, in each branch of vector power amplifier **700**.

[0249] The outputs of PAs **770**, **772**, **774**, and **776** are coupled together to generate output signal **782** of vector power amplifier **700**. In an embodiment, the outputs of PAs **770**, **772**, **774**, and **776** are directly coupled together using a wire. Direct coupling in this manner means that there is minimal or no resistive, inductive, or capacitive isolation between the outputs of PAs **770**, **772**, **774**, and **776**. In other words, outputs of PAs **770**, **772**, **774**, and **776**, are coupled together without intervening components. Alternatively, in an embodiment, the outputs of PAs **770**, **772**, **774**, and **776** are coupled together indirectly through inductances and/or capacitances that result in low or minimal impedance connections, and/or connections that result in minimal isolation and minimal power loss. Alternatively, outputs of PAs **770**, **772**, **774**, and **776** are coupled using well known combining techniques, such as Wilkinson, hybrid, transformers, or known active combiners. In an embodiment, the PAs **770**, **772**, **774**, and **776** provide integrated amplification and power combining in a single operation. In an embodiment, one or more of the power amplifiers and/or drivers described herein are implemented using multiple input, single output power amplification techniques, examples of which are shown in FIGS. **7**B, and **51**A-H.

[0250] Output signal **782** includes the I and Q characteristics of I and Q information signals **702** and **704**. Further, output signal **782** is of the same frequency as that of its constituents, and thus is of the desired up-converted output frequency. In embodiments of vector power amplifier **700**, a pull-up impedance **780** is coupled between the output of vector amplifier **700** and a power supply. Output stage embodiments according to power amplification methods and systems of the present invention will be further described below in section 3.5.

[0251] In other embodiments of vector power amplifier **700**, process detectors are employed to compensate for any process variations in circuitry of the amplifier. In the embodiment of FIG. **7**A for example, process detectors **791-793** are optionally added to monitor variations in PA drivers **794-797** and phase splitter **750**. In further embodiments, frequency compensation circuitry **799** may be employed to compensate for frequency variations.

[0252] FIG. **7**B is a block diagram that illustrates another exemplary embodiment of vector power amplifier **700**. Optional components are illustrated with dashed lines, although other embodiments may have more or less optional components.

[0253] The embodiment illustrates a multiple-input single-output (MISO) implementation of the amplifier of FIG. **7**A. In the embodiment of FIG. **7**B, constant envelope signals **761**, **763**, **765** and **767**, output from vector modulators **760**, **762**, **764**, and **766**, are input into MISO PAs **784** and **786**. MISO PAs **784** and **786** are two-input single-output power amplifiers. In an embodiment, MISO PAs **784** and **786** include elements **770**, **772**, **774**, **776**, **794-797** as shown in the embodiment of FIG. **7**A or functional equivalence thereof. In another embodiment, MISO PAs **784** and **786** may include other elements, such as optional pre-drivers and optional process detection circuitry. Further, MISO PAs **784** and **786** are not limited to being two-input PAs as shown in FIG. **7**B. In other embodiments as will be described further below with reference to FIGS. **51**A-H, PAs **784** and **786** can have any number of inputs and outputs.

[0254] FIG. **8**A is a block diagram that illustrates another exemplary embodiment **800**A of a vector power amplifier according to the Cartesian 4-Branch VPA method shown in FIG. **6**. Optional components are illustrated with dashed lines, although other embodiments may have more or less optional components.

[0255] In the embodiment of FIG. **8**A, a DAC **830** of sufficient resolution and sample rate replaces DACs **730**, **732**, **734**, and **736** of the embodiment of FIG. **7**A. DAC **830**'s sample rate is controlled by a DAC clock signal **826**.

[0256] DAC **830** receives in-phase and quadrature information signals **810** and **820** from I Data Transfer Function module **710** and Q Data Transfer Function module **712**, respectively, as described above. In an embodiment, a input selector **822** selects the order of signals **810** and **820** being input into DAC **830**.

[0257] DAC **830** may output a single analog signal at a time. In an embodiment, a sample and hold architecture may be used to ensure proper signal timing to the four branches of the amplifier, as shown in FIG. **8**A.

[0258] DAC **830** sequentially outputs analog signals **832**, **834**, **836**, **838** to a first set of sample-and-hold circuits **842**, **844**, **846**, and **848**. In an embodiment, DAC **830** is clocked at a sufficient rate to emulate the operation of DACs **730**, **732**, **734**, and **736** of the embodiment of FIG. **7**A. An output selector **824** determines which of output signals **832**, **834**, **836**, and **838** should be selected for output.

[0259] DAC **830**'s DAC clock signal **826**, output selector signal **824**, input selector **822**, and sample-and-hold clocks **840**A-D, and **850** are controlled by a control module that can be independent or integrated into transfer function modules **710** and/or **712**.

[0260] In an embodiment, sample-and-hold circuits (S/H) **842**, **844**, **846**, and **848** sample and hold the received analog values from DAC **830** according to a clock signals **840**A-D. Sample-and-hold circuits **852**, **854**, **856**, and **858** sample and hold the analog values from sample and hold circuits **842**, **844**, **846**, and **848** respectively. In turn, sample-and-hold circuits **852**, **854**, **856**, and **858** hold the received analog values, and simultaneously release the values to vector modulators **760**, **762**, **764**, and **766** according to a common clock signal **850**. In another embodiment, sample-and-hold circuits **852**, **854**, **856**, and **858** release the values to optional interpolation filters **731**, **733**, **735**, and **737** which are also anti-aliasing filters. In an embodiment, a common clock signal **850** is used in order to ensure that the outputs of S/H **852**, **854**, **856**, and **858** are time-aligned.

[0261] Other aspects of vector power amplifier **800**A substantially correspond to those described above with respect to vector power amplifier **700**.

[0262] FIG. **8**B is a block diagram that illustrates another exemplary embodiment **800**B of a vector power amplifier according to the Cartesian 4-Branch VPA method shown in FIG. **6**. Optional components are illustrated with dashed lines, although other embodiments may have more or less optional components.

[0263] Embodiment **800**B illustrates another single DAC implementation of the vector power amplifier. However, in contrast to the embodiment of FIG. **8**A, the sample and hold architecture includes a single set of sample-and-hold (S/H) circuits. As shown in FIG. **8**B, S/H **842**, **844**, **846**, and **848** receive analog values from DAC **830**, illustrated as signals **832**, **834**, **836**, and **838**. Each of S/H circuits **842**, **844**, **846** and **848** release its received value according to a different clock **840**A-D as shown. The time difference between analog samples used for to generate signals **740**, **741**, **742**, **744**, **745**, and **746** can be compensated for in transfer functions **710** and **712**. According to the embodiment of FIG. **8**B, one level of S/H circuitry can be eliminated relative to the embodiment of FIG. **8**A, thereby reducing the size and the complexity of the amplifier.

[0264] Other aspects of vector power amplifier **800**B substantially correspond to those described above with respect to vector power amplifiers **700** and **800**A.

[0265] FIG. **8**C is a block diagram that illustrates another exemplary embodiment **800**C of vector power amplifier **700**. Optional components are illustrated with dashed lines, although other embodiments may have more or less optional components. The embodiment of FIG. **8**C illustrates a multiple-input single-output (MISO) implementation of the amplifier of FIG. **8**A. In the embodiment of FIG. **8**C, constant envelope signals **761**, **763**, **765** and **767**, output from vector modulators **760**, **762**, **764**, and **766**, are input into MISO PAs **860** and **862**. MISO PAs **860** and **862** are two-input single-output power amplifiers. In an embodiment, MISO PAs **860** and **862** include elements **770**, **772**, **774**, **776**, **794-797** as shown in the embodiment of FIG. **7**A or functional equivalence thereof. In another embodiment, MISO PAs **860** and **862** may include other elements, such as optional pre-drivers and optional process detection circuitry. In another embodiment, MISO PAs **860** and **862** may include other elements, such as pre-drivers, not shown in the embodiment of FIG. **7**A. Further, MISO PAs **860** and **862** are not limited to being two-input PAs as shown in FIG. **8**C. In other embodiments as will be described further below with reference to FIGS. **51**A-H, PAs **860** and **862** can have any number of inputs and outputs.

[0266] Other aspects of vector power amplifier **800**C substantially correspond to those described above with respect to vector power amplifiers **700** and **800**A.

[0267] FIG. **8**D is a block diagram that illustrates another exemplary embodiment **800**D of vector power amplifier **700**. Optional components are illustrated with dashed lines, although other embodiments may have more or less optional components. The embodiment of FIG. **8**D illustrates a multiple-input single-output (MISO) implementation of the amplifier of FIG. **8**B. In the embodiment of FIG. **8**D, constant envelope signals **761**, **763**, **765** and **767**, output from vector modulators **760**, **762**, **764**, and **766**, are input into MISO PAs **870** and **872**. MISO PAs **870** and **872** are two-input single-output power amplifiers. In an embodiment, MISO PAs **870** and **872** include elements **770**, **772**, **774**, **776**, **794-797** as shown in the embodiment of FIG. **7**A or functional equivalence thereof. In another embodiment, MISO PAs **870** and **872** may include other elements, such as optional pre-drivers and optional process detection circuitry. In another embodiment, MISO PAs **870** and **872** may include other elements, such as pre-drivers, not shown in the embodiment of FIG. **7**A. Further, MISO PAs **870** and **872** are not limited to being two-input PAs as shown in FIG. **8**D. In other embodiments as will be described further below with reference to FIGS. **51**A-H, PAs **870** and **872** can have any number of inputs and outputs.

[0268] Other aspects of vector power amplifier **800**D substantially correspond to those described above with respect to vector power amplifiers **700** and **800**B.

3.2) Cartesian-Polar Cartesian-Polar 2-Branch Vector Power Amplifier

[0269] A Cartesian-Polar-Cartesian-Polar (CPCP) 2-Branch VPA embodiment shall now be described (The name of this embodiment is provided for ease of reference, and is not limiting).

[0270] According to the Cartesian-Polar-Cartesian-Polar (CPCP) 2-Branch VPA method, a time-varying complex envelope signal is decomposed into 2 substantially constant envelope constituent signals. The constituent signals are individually amplified, and then summed to construct an amplified version of the original time-varying complex envelope signal. In addition, the phase angle of the time-varying complex envelope signal is determined and the resulting summation of the constituent signals are phase shifted by the appropriate angle.

[0271] In one embodiment of the CPCP 2-Branch VPA method, a magnitude and a phase angle of a time-varying complex envelope signal are calculated from in-phase and quadrature components of a signal. Given the magnitude information, two substantially constant envelope constituents are calculated from a normalized version of the desired time-varying envelope signal, wherein the normalization includes implementation specific manipulation of phase and/or amplitude. The two substantially constant envelope constituents are then phase shifted by an appropriate angle related to the phase shift of the desired time-varying envelope signal. The substantially constant envelope constituents are then individually amplified substantially equally, and summed to generate an amplified version of the original desired time-varying envelope signal.

[0272] FIGS. **9**A and **9**B conceptually illustrate the CPCP 2-Branch VPA embodiment using a phasor signal representation. In FIG. **9**A, phasor $\vec{R}_{in}$ represents a time-varying complex envelope input signal r(t). At any instant of time, $\vec{R}_{in}$ reflects a magnitude and a phase shift angle of signal r(t). In the example shown in FIG. **9**A, $\vec{R}_{in}$ is characterized by a magnitude R and a phase shift angle θ. As described above, the phase shift angle is measured relative to a reference signal.

[0273] Referring to FIG. **9**A, $\vec{R}'$ represents the relative amplitude component of $\vec{R}_{in}$ generated by $\vec{U}'$ and $\vec{L}'$.

[0274] Still referring to FIG. **9**A, it is noted that, at any time instant, $\vec{R}'$ can be obtained by the sum of an upper phasor $\vec{U}'$ and a lower phasor $\vec{L}'$. Further, $\vec{U}'$ and $\vec{L}'$ can be maintained to have substantially constant magnitude. The phasors, $\vec{U}'$ and $\vec{L}'$, accordingly, represent two substantially constant envelope signals. r'(t) can thus be obtained, at any time instant, by the sum of two substantially constant envelope signals that correspond to phasors $\vec{U}'$ and $\vec{L}'$.

[0275] The phase shifts of phasors $\vec{U}'$ and $\vec{L}'$ relative to $\vec{R}'$ are set according to the desired magnitude R of $\vec{R}'$. In the simplest case, when upper and lower phasors $\vec{U}'$ and $\vec{L}'$ are selected to have equal magnitude, upper and lower phasors $\vec{U}'$ and $\vec{L}'$ are substantially symmetrically shifted in phase relative to $\vec{R}'$. This is illustrated in the example of FIG. **9**A. It is noted that terms and phrases indicating or suggesting orientation, such as but not limited to "upper and lower" are used herein for ease of reference and are not functionally or structurally limiting.

[0276] It can be verified that, for the case illustrated in FIG. **9**A, the phase shift of $\vec{U}'$ and $\vec{L}'$ relative to $\vec{R}'$, illustrated as angle

$$\frac{\phi}{2}$$

in FIG. **9**A, is related to the magnitude of $\vec{R}'$ as follows:

$$\frac{\phi}{2}=\cot^{-1}\left(\frac{R}{2\sqrt{1-\frac{R^2}{4}}}\right) \tag{7}$$

where R represents a normalized magnitude of phasor $\vec{R}'$.

[0277] Equation (7) can further be reduced to

$$\frac{\phi}{2}=\cos^{-1}\left(\frac{R}{2}\right) \tag{7.10}$$

where R represents a normalized magnitude of phasor $\vec{R}'$.

[0278] Alternatively, any substantially equivalent mathematical equations or other substantially equivalent mathematical techniques such as look up tables can be used.

[0279] It follows from the above discussion that, in phasor representation, any phasor $\vec{R}'$ of variable magnitude and phase can be constructed by the sum of two constant magnitude phasor components:

$$\vec{R}'=\vec{U}'+\vec{L}'|\vec{U}|=|\vec{L}|=A=\text{constant} \tag{8}$$

[0280] Correspondingly, in the time domain, a time-varying envelope sinusoidal signal r'(t)=R(t)×cos(ωt) is constructed by the sum of two constant envelope signals as follows:

$$r'(t)=U'(t)+L'(t); \tag{9}$$
$$U'(t)=A\times\cos\left(\omega t+\frac{\phi}{2}\right);$$
$$L'(t)=A\times\cos\left(\omega t-\frac{\phi}{2}\right);$$

where A is a constant and

$$\frac{\phi}{2}$$

is as shown in equation (7).

[0281] From FIG. **9**A, it can be further verified that equations (9) can be rewritten as:

$$r'(t)=U'(t)+L'(t);$$
$$U'(t)=C\cos(\omega t)+\alpha\sin(\omega t);$$
$$L'(t)=C\cos(\omega t)-\beta\sin(\omega t); \tag{10}$$

where C denotes the real part component of phasors $\vec{U}'$ and $\vec{L}'$ and is equal to

$$A \times \cos\left(\frac{\phi}{2}\right).$$

Note that C is a common component of $\overrightarrow{U'}$ and $\overrightarrow{L'}$. α and β denote the imaginary part components of phasors $\overrightarrow{U'}$ and $\overrightarrow{L'}$, respectively.

[0282]

$$\alpha = \beta = A \times \sin\left(\frac{\phi}{2}\right).$$

Accordingly, from equations (12),

[0283]

$$r'(t) = 2C \times \cos(\omega t) = 2A \times \cos\left(\frac{\phi}{2}\right) \times \cos(\omega t).$$

As understood by a person skilled in the art based on the teachings herein, other equivalent and/or simplified representations of the above representations of the quantities A, B, and C may also be used, including look up tables, for example.

[0284] Note that $\overrightarrow{R_{in}}$ is shifted by θ degrees relative to $\overrightarrow{R'}$. Accordingly, using equations (8), it can be deduced that:

$$\overrightarrow{R_{in}} = \overrightarrow{R'}e^{j\theta} = (\overrightarrow{U'} + \overrightarrow{L'})e^{j\theta} = \overrightarrow{U'}e^{j\theta + \overrightarrow{L'}ej\theta} \tag{11}$$

[0285] Equations (11) imply that a representation of $\overrightarrow{R_{in}}$ can be obtained by summing phasors $\overrightarrow{U'}$ and $\overrightarrow{L'}$, described above, shifted by θ degrees. Further, an amplified output version, $\overrightarrow{R_{out}}$, of $\overrightarrow{R_{in}}$ can be obtained by separately amplifying substantially equally each of the θ degrees shifted versions of phasors $\overrightarrow{U'}$ and $\overrightarrow{\ '}$, and summing them. FIG. **9**B illustrates this concept. In FIG. **9**B, phasors $\overrightarrow{U}$ and $\overrightarrow{L}$ represent θ degrees shifted and amplified versions of phasors $\overrightarrow{U'}$ and $\overrightarrow{L'}$. Note that, since $\overrightarrow{U'}$ and $\overrightarrow{L'}$ are constant magnitude phasors, $\overrightarrow{U}$ and $\overrightarrow{L}$ are also constant magnitude phasors. Phasors $\overrightarrow{U}$ and $\overrightarrow{L}$ sum, as shown FIG. **9**B, to phasor $\overrightarrow{R_{out}}$, which is a power amplified version of input signal $\overrightarrow{R_{in}}$.

[0286] Equivalently, in the time domain, it can be shown that:

$$r_{out}(t) = U(t) + L(t);$$

$$U(t) = K[C\cos(\omega t+\theta) + \alpha\sin(\omega t+\theta)];$$

$$L(t) = K\cdot[C\cos(\omega t+\theta) - \beta\sin(\omega t+\theta)]. \tag{12}$$

where $r_{out}(t)$ corresponds to the time domain signal represented by phasor $\overrightarrow{R_{out}}$, U(t) and L(t) correspond to the time domain signals represents by phasors $\overrightarrow{U}$ and $\overrightarrow{L}$, and K is the power amplification factor.

[0287] A person skilled in the art will appreciate that, whereas the time domain representations in equations (9) and (10) have been provided for the case of a sinusoidal waveform, equivalent representations can be developed for non-sinusoidal waveforms using appropriate basis functions.

[0288] FIG. **10** is a block diagram that conceptually illustrates an exemplary embodiment **1000** of the CPCP 2-Branch VPA embodiment. An output signal r(t) of desired power level and frequency characteristics is generated from in-phase and quadrature components according to the CPCP 2-Branch VPA embodiment.

[0289] In the example of FIG. **10**, a clock signal **1010** represents a reference signal for generating output signal r(t). Clock signal **1010** is of the same frequency as that of desired output signal r(t).

[0290] Referring to FIG. **10**, an Iclk_phase signal **1012** and a Qclk_phase signal **1014** represent amplitude analog values that are multiplied by the in-phase and quadrature components of Clk signal **1010** and are calculated from the baseband I and Q signals.

[0291] Still referring to FIG. **10**, clock signal **1010** is multiplied with Iclk_phase signal **1012**. In parallel, a 90° degrees shifted version of clock signal **1010** is multiplied with Qclk_phase signal **1014**. The two multiplied signals are combined to generate Rclk signal **1016**. Rclk signal **1016** is of the same frequency as clock signal **1010**. Further, Rclk signal **1016** is characterized by a phase shift angle according to the ratio of Q(t) and I(t). The magnitude of Rclk signal **1016** is such that $R^2clk = I^2clk\_phase + Q^2clk\_phase$. Accordingly, Rclk signal **1016** represents a substantially constant envelope signal having the phase characteristics of the desired output signal r(t).

[0292] Still referring to FIG. **10**, Rclk signal **1016** is input, in parallel, into two vector modulators **1060** and **1062**. Vector modulators **1060** and **1062** generate the U(t) and L(t) substantially constant envelope constituents, respectively, of the desired output signal r(t) as described in (12). In vector modulator **1060**, an in-phase Rclk signal **1020**, multiplied with Common signal **1028**, is combined with a 90° degree shifted version **1018** of Rclk signal, multiplied with first signal **1026**. In parallel, in vector modulator **1062**, an in-phase Rclk signal **1022**, multiplied with Common signal **1028**, is combined with a 90° degrees shifted version **1024** of Rclk signal, multiplied with second signal **1030**. Common signal **1028**, first signal **1026**, and second signal **1030** correspond, respectively, to the real part C and the imaginary parts α and β described in equation (12).

[0293] Output signals **1040** and **1042** of respective vector modulators **1060** and **1062** correspond, respectively, to the U(t) and L(t) constant envelope constituents of input signal r(t).

[0294] As described above, signals **1040** and **1042** are characterized by having substantially equal and constant magnitude envelopes. Accordingly, when signals **1040** and **1042** are input into corresponding power amplifiers (PA) **1044** and **1046**, corresponding amplified signals **1048** and **1050** are substantially constant envelope signals.

[0295] Power amplifiers **1044** and **1046** apply substantially equal power amplification to signals **1040** and **1042**, respectively. In an embodiment, the power amplification level of PAs **1044** and **1046** is set according to the desired power level of output signal r(t). Further, amplified signals **1048** and **1050** are in-phase relative to each other. Accordingly, when summed together, as shown in FIG. **10**, resulting signal **1052** corresponds to the desired output signal r(t).

[0296] FIG. **10**A is another exemplary embodiment **1000**A of the CPCP 2-Branch VPA embodiment. Embodiment **1000**A represents a Multiple Input Single Output (MISO) implementation of embodiment **1000** of FIG. **10**.

[0297] In embodiment **1000**A, constant envelope signals **1040** and **1042**, output from vector modulators **1060** and **1062**, are input into MISO PA **1054**. MISO PA **1054** is a two-input single-output power amplifier. In an embodiment, MISO PA **1054** may include various elements, such as pre-drivers, drivers, power amplifiers, and process detectors (not shown in FIG. **10**A), for example. Further, MISO PA **1054** is not limited to being a two-input PA as shown in FIG. **10**A. In other embodiments, as will be described further below with reference to FIGS. **51**A-H, PA **1054** can have any number of inputs.

[0298] Operation of the CPCP 2-Branch VPA embodiment is depicted in the process flowchart **1100** of FIG. **11**.

[0299] The process begins at step **1110**, which includes receiving a baseband representation of the desired output signal. In an embodiment, this involves receiving in-phase (I) and quadrature (Q) components of the desired output signal. In another embodiment, this involves receiving magnitude and phase of the desired output signal.

[0300] Step **1120** includes receiving a clock signal set according to a desired output signal frequency of the desired output signal. In the example of FIG. **10**, step **1120** is achieved by receiving clock signal **1010**.

[0301] Step **1130** includes processing the clock signal to generate a normalized clock signal having a phase shift angle according to the received I and Q components. In an embodiment, the normalized clock signal is a constant envelope signal having a phase shift angle according to a ratio of the I and Q components. The phase shift angle of the normalized clock is relative to the original clock signal. In the example of FIG. **10**, step **1130** is achieved by multiplying clock signal **101O**'s in-phase and quadrature components with Iclk_phase **1012** and Qclk_phase **1014** signals, and then summing the multiplied signal to generate Rclk signal **1016**.

[0302] Step **1140** includes the processing of the I and Q components to generate the amplitude information required to produce first and second substantially constant envelope constituent signals.

[0303] Step **1150** includes processing the amplitude information of step **1140** and the normalized clock signal Rclk to generate the first and second constant envelope constituents of the desired output signal. In an embodiment, step **1150** involves phase shifting the first and second constant envelope constituents of the desired output signal by the phase shift angle of the normalized clock signal. In the example of FIG. **10**, step **1150** is achieved by vector modulators **1060** and **1062** modulating Rclk signal **1016** with first signal **1026**, second signal **1030**, and common signal **1028** to generate signals **1040** and **1042**.

[0304] Step **1160** includes individually amplifying the first and second constant envelope constituents, and summing the amplified signals to generate the desired output signal. In an embodiment, the amplification of the first and second constant envelope constituents is substantially equal and according to a desired power level of the desired output signal. In the example of FIG. **10**, step **1160** is achieved by PAs **1044** and **1046** amplifying signals **1040** and **1042** to generate amplified signals **1048** and **1050**.

[0305] FIG. **12** is a block diagram that illustrates an exemplary embodiment of a vector power amplifier **1200** implementing the process flowchart **1100**. Optional components are illustrated with dashed lines, although in other embodiments more or less components may be optional.

[0306] Referring to FIG. **12**, in-phase (I) and quadrature (Q) information signal **1210** is received by an I and Q Data Transfer Function module **1216**. In an embodiment, I and Q Data Transfer Function **1216** samples signal **1210** according to a sample clock **1212**. I and Q information signal **1210** includes baseband I and Q information of a desired output signal r(t).

[0307] In an embodiment, I and Q Data Transfer Function module **1216** processes information signal **1210** to generate information signals **1220**, **1222**, **1224**, and **1226**. The operation of I and Q Data Transfer Function module **1216** is further described below in section 3.4.

[0308] Referring to FIG. **12**, information signal **1220** includes quadrature amplitude information of first and second constant envelope constituents of a baseband version of desired output signal r(t). With reference to FIG. **9**A, for example, information signal **1220** includes the α and β quadrature components. Referring again to FIG. **12**, information signal **1226** includes in-phase amplitude information of the first and second constant envelope constituents of the baseband version of signal r(t). With reference to FIG. **9**A, for example, information signal **1226** includes the common C in-phase component.

[0309] Still referring to FIG. **12**, information signals **1222** and **1224** include normalized in-phase Iclk_phase and quadrature Qclk_phase signals, respectively. Iclk_phase and Qclk_phase are normalized versions of the I and Q information signals included in signal **1210**. In an embodiment, Iclk_phase and Qclk_phase are normalized such that that (I^2clk_phase+Q^2clk_phase=constant). It is noted that the phase of signal **1250** corresponds to the phase of the desired output signal and is created from Iclk_phase and Qclk_phase. Referring to FIG. **9**B, Iclk_phase and Qclk_phase are related to I and Q as follows:

$$\theta = \tan^{-1}\left(\frac{Q}{I}\right) = \tan^{-1}\left(\frac{Q_{\text{clk\_phase}}}{I_{\text{clk\_phase}}}\right)$$

(12.1)

where θ represents the phase of the desired output signal, represented b

[0310] phasor $\overrightarrow{R_{out}}$ in FIG. **9**B. The sign information of the baseband I and Q information must be taken into account to calculate θ for all four quadrants.

[0311] In the exemplary embodiment of FIG. **12**, information signals **1220**, **1222**, **1224**, and **1226** are digital signals. Accordingly, each of signals **1220**, **1222**, **1224**, and **1226** is fed into a corresponding digital-to-analog converter (DAC) **1230**, **1232**, **1234**, and **1236**. The resolution and sample rate of DACs **1230**, **1232**, **1234**, and **1236** is selected according to specific signaling schemes. DACs **1230**, **1232**, **1234**, and **1236** are controlled by DAC clock signals **1221**, **1223**, **1225**, and **1227**, respectively. DAC clock signals **1221**, **1223**, **1225**, and **1227** may be derived from a same clock signal or may be independent.

[0312] In other embodiments, information signals **1220**, **1222**, **1224**, and **1226** are generated in analog format and no DACs are required.

[0313] Referring to FIG. **12**, DACs **1230**, **1232**, **1234**, and **1236** convert digital information signals **1220**, **1222**, **1224**, and **1226** into corresponding analog signals, and input these analog signal into optional interpolation filters **1231**, **1233**, **1235**, and **1237**, respectively. Interpolation filters **1231**, **1233**, **1235**, and **1237**, which also serve as anti-aliasing filters, shape the DACs output signals to produce the desired output waveform. Interpolation filters **1231**, **1233**, **1235**, and **1237** generate signals **1240**, **1244**, **1246**, and **1248**, respectively. Signal **1242** represents the inverse of signal **1240**.

[0314] Still referring to FIG. **12**, signals **1244** and **1246**, which include Iclk_phase and Qclk_phase information, are input into a vector modulator **1238**. Vector modulator **1238** multiplies signal **1244** with a channel clock signal **1214**. Channel clock signal **1214** is selected according to a desired output signal frequency. In parallel, vector modulator **1238** multiplies signal **1246** with a 90° shifted version of channel clock signal **1214**. In other words, vector modulator **1238** generates an in-phase component having amplitude of Iclk_phase and a quadrature component having amplitude of Qclk_phase.

[0315] Vector modulator **1238** combines the two modulated signals to generate Rclk signal **1250**. Rclk signal **1250** is a substantially constant envelope signal having the desired output frequency and a phase shift angle according to the I and Q data included in signal **1210**.

[0316] Still referring to FIG. **12**, signals **1240**, **1242**, and **1248** include the U, L, and Common C amplitude components, respectively, of the complex envelope of signal r(t). Signals **1240**, **1242**, and **1248** along with Rclk signal **1250** are input into vector modulators **1260** and **1262**.

[0317] Vector modulator **1260** combines signal **1240**, multiplied with a 90° shifted version of Rclk signal **1250**, and signal **1248**, multiplied with a 0° shifted version of Rclk signal **1250**, to generate output signal **1264**. In parallel, vector modulator **1262** combines signal **1242**, multiplied with a 90° shifted version of Rclk signal **1250**, and signal **1248**, modulated with a 0° shifted version of Rclk signal **1250**, to generate output signal **1266**.

[0318] Output signals **1264** and **1266** represent substantially constant envelope signals. Further, phase shifts of output signals **1264** and **1266** relative to Rclk signal **1250** are determined by the angle relationships associated with the ratios α/C and β/C, respectively. In an embodiment, $\alpha=-\beta$ and therefore output signals **1264** and **1266** are symmetrically phased relative to Rclk signal **1250**. With reference to FIG. **9**B, for example, output signals **1264** and **1266** correspond, respectively, to the $\vec{U}$ and $\vec{L}$ constant magnitude phasors.

[0319] A sum of output signals **1264** and **1266** results in a channel-clock-modulated signal having the I and Q characteristics of baseband signal r(t). To achieve a desired power level at the output of vector power amplifier **1200**, however, signals **1264** and **1266** are amplified to generate an amplified output signal. In the embodiment of FIG. **12**, signals **1264** and **1266** are, respectively, input into power amplifiers (PAs) **1270** and **1272** and amplified. In an embodiment, PAs **1270** and **1272** include switching power amplifiers. Autobias circuitry **1218** controls the bias of PAs **1270** and **1272** as further described below in section 3.5.2. In the embodiment of FIG. **12**, for example, autobias circuitry **1218** provides a bias voltage **1228** to PAs **1270** and **1272**.

[0320] In an embodiment, PAs **1270** and **1272** apply substantially equal power amplification to respective constant envelope signals **1264**-**1266**. In an embodiment, the power amplification is set according to the desired output power level. In other embodiments of vector power amplifier **1200**, PA drivers and/or pre-drivers are additionally employed to provide additional power amplification capability to the amplifier. In the embodiment of FIG. **12**, for example, PA drivers **1284** and **1286** are optionally added, respectively, between vector modulators **1260** and **1262** and subsequent PAs **1270** and **1272**.

[0321] Respective output signals **1274** and **1276** of PAs **1270** and **1272** are substantially constant envelope signals. Further, when output signals **1274** and **1276** are summed, the resulting signal has minimal non-linear distortion. In the embodiment of FIG. **12**, output signals **1274** and **1276** are coupled together to generate output signal **1280** of vector power amplifier **1200**. In an embodiment, no isolation is used in coupling the outputs of PAs **1270** and **1272**. Accordingly, minimal power loss is incurred by the coupling. In an embodiment, the outputs of PAs **1270** and **1272** are directly coupled together using a wire. Direct coupling in this manner means that there is minimal or no resistive, inductive, or capacitive isolation between the outputs of PAs **1270** and **1272**. In other words, outputs of PAs **1270** and **1272** are coupled together without intervening components. Alternatively, in an embodiment, the outputs of PAs **1270** and **1272** are coupled together indirectly through inductances and/or capacitances that result in low or minimal impedance connections, and/or connections that result in minimal isolation and minimal power loss. Alternatively, outputs of PAs **1270** and **1272** are coupled using well known combining techniques, such as Wilkinson, hybrid combiners, transformers, or known active combiners. In an embodiment, the PAs **1270** and **1272** provide integrated amplification and power combining in a single operation. In an embodiment, one or more of the power amplifiers and/or drivers described herein are implemented using multiple input, single output power amplification techniques, examples of which are shown in FIGS. **12**A, **12**B, and **51**A-H.

[0322] Output signal **1280** represents a signal having the I and Q characteristics of baseband signal r(t) and the desired output power level and frequency. In embodiments of vector power amplifier **1200**, a pull-up impedance **1288** is coupled between the output of vector power amplifier **1200** and a power supply. In other embodiments, an impedance matching network **1290** is coupled at the output of vector power amplifier **1200**. Output stage embodiments according to power amplification methods and systems of the present invention will be further described below in section 3.5.

[0323] In other embodiments of vector power amplifier **1200**, process detectors are employed to compensate for any process variations in circuitry of the amplifier. In the exemplary embodiment of FIG. **12**, for example, process detector **1282** is optionally added to monitor variations in PA drivers **1284** and **1286**.

[0324] FIG. **12**A is a block diagram that illustrates another exemplary embodiment of a vector power amplifier **1200**A implementing the process flowchart **1100**. Optional components are illustrated with dashed lines, although in other embodiments more or less components may be optional.

[0325] Embodiment **1200**A illustrates a multiple-input single-output (MISO) implementation of embodiment **1200**. In embodiment **1200**A, constant envelope signals **1261** and **1263**, output from vector modulators **1260** and **1262**, are input into MISO PA **1292**. MISO PA **1292** is a two-input single-output power amplifier. In an embodiment, MISO PA **1292** includes elements **1270**, **1272**, **1282**, **1284**, and **1286** as shown in the embodiment of FIG. **12**. In another embodiment, MISO PA **1292** may include other elements, such as pre-drivers, not shown in the embodiment of FIG. **12**. Further, MISO PA **1292** is not limited to being a two-input PA as shown in FIG. **12**A. In other embodiments as will be described further below with reference to FIGS. **51**A-H, PA **1292** can have any number of inputs and outputs.

[0326] Still referring to FIG. **12**A, embodiment **1200**A illustrates one implementation for delivering autobias signals to MISO PA **1292**. In the embodiment of FIG. **12**A, Autobias signal **1228** generated by Autobias circuitry **1218**, has one or more signals derived from it to bias different stages of MISO PA **1292**. As shown in the example of FIG. **12**A, three bias control signals Bias A, Bias B, and Bias C are derived from Autobias signal **1228**, and then input at different stages of MISO PA **1292**. For example, Bias C may be the bias signal to the pre-driver stage of MISO PA **1292**. Similarly, Bias B and Bias A may be the bias signals to the driver and PA stages of MISO PA **1292**.

[0327] In another implementation, shown in embodiment **1200**B of FIG. **12** B, Autobias circuitry **1218** generates separate Autobias signals **1295**, **1296**, and **1295**, corresponding to Bias A, Bias B, and Bias C, respectively. Signals **1295**, **1296**, and **1297** may or may not be generated separately within Autobias circuitry **1218**, but are output separately as shown. Further, signals **1295**, **1296**, and **1297** may or may not be related as determined by the biasing of the different stages of MISO PA **1294**.

[0328] Other aspects of vector power amplifiers **1200**A and **1200**B substantially correspond to those described above with respect to vector power amplifier **1200**.

[0329] FIG. **13** is a block diagram that illustrates another exemplary embodiment **1300** of a vector power amplifier according to the CPCP 2-Branch VPA embodiment. Optional components are illustrated with dashed lines, although in other embodiments more or less components may be optional.

[0330] In the exemplary embodiment of FIG. **13**, a DAC of sufficient resolution and sample rate **1320** replaces DACs **1230**, **1232**, **1234** and **1236** of the embodiment of FIG. **12**. DAC **1320** is controlled by a DAC clock **1324**.

[0331] DAC **1320** receives information signal **1310** from I and Q Data Transfer Function module **1216**. Information signal **1310** includes identical information content to signals **1220**, **1222**, **1224** and **1226** in the embodiment of FIG. **12**.

[0332] DAC **1320** may output a single analog signal at a time. Accordingly, a sample-and-hold architecture may be used as shown in FIG. **13**.

[0333] DAC **1320** sequentially outputs analog signals **1332**, **1334**, **1336**, **1336** to a first set of sample-and-hold circuits **1342**, **1344**, **1346**, and **1348**. In an embodiment, DAC **1230** is clocked at a sufficient rate to replace DACs **1230**, **1232**, **1234**, and **1236** of the embodiment of FIG. **12**. An output selector **1322** determines which of output signals **1332**, **1334**, **1336**, and **1338** should be selected for output.

[0334] DAC **1320**'s DAC clock signal **1324**, output selector signal **1322**, and sample-and-hold clocks **1340**A-D and **1350** are controlled by a control module that can be independent or integrated into transfer function module **1216**.

[0335] In an embodiment, sample-and-hold circuits (S/H) **1342**, **1344**, **1346**, and **1348** hold the received analog values and, according to a clock signal **1340**A-D, release the values to a second set of sample-and-hold circuits **1352**, **1354**, **1356**, and **1358**. For example, S/H **1342** release its value to S/H **1352** according to a received clock signal **1340**A. In turn, sample-and-hold circuits **1352**, **1354**, **1356**, and **1358** hold the received analog values, and simultaneously release the values to interpolation filters **1231**, **1233**, **1235**, and **1237** according to a common clock signal **1350**. A common clock signal **1350** is used in order to ensure that the outputs of S/H **1352**, **1354**, **1356**, and **1358** are time-aligned.

[0336] In another embodiment, a single layer of S/H circuitry that includes S/H **1342**, **1344**, **1346**, and **1348** can be employed. Accordingly, S/H circuits **1342**, **1344**, **1346**, and **1348** receive analog values from DAC **1320**, and each releases its received value according to a clock independent of the others. For example, S/H **1342** is controlled by clock **1340**A, which may not be synchronized with clock **1340**B that controls S/H **1344**. To ensure that outputs of S/H circuits **1342**, **1344**, **1346**, and **1348** are time-aligned, delays between clocks **1340**A-D are pre-compensated for in prior stages of the amplifier. For example, DAC **1320** outputs signal **1332**, **1334**, **1336**, and **1338** with appropriately selected delays to S/H circuits **1342**, **1344**, **1346**, and **1348** in order to compensate for the time differences between clocks **1340**A-D.

[0337] Other aspects of vector power amplifier **1300** are substantially equivalent to those described above with respect to vector power amplifier **1200**.

[0338] FIG. **13**A is a block diagram that illustrates another exemplary embodiment **1300**A of a vector power amplifier according to the CPCP 2-Branch VPA embodiment. Optional components are illustrated with dashed lines, although in other embodiments more or less components may be optional. Embodiment **1300**A is a MISO implementation of embodiment **1300** of FIG. **13**.

[0339] In the embodiment of FIG. **13**A, constant envelope signals **1261** and **1263** output from vector modulators **1260** and **1262** are input into MISO PA **1360**. MISO PA **1360** is a two-input single-output power amplifier. In an embodiment, MISO PA **1360** includes elements **1270**, **1272**, **1282**, **1284**, and **1286** as shown in the embodiment of FIG. **13**. In another embodiment, MISO PA **1360** may include other elements, such as pre-drivers, not shown in the embodiment of FIG. **13**, or functional equivalents thereof. Further, MISO PA **1360** is not limited to being a two-input PA as shown in FIG. **13**A. In other embodiments as will be described further below with reference to FIGS. **51**A-H, PA **1360** can have any number of inputs.

[0340] The embodiment of FIG. **13**A further illustrates two different sample and hold architectures with a single or two levels of S/H circuitry as shown. The two implementations have been described above with respect to FIG. **13**.

[0341] Embodiment **1300**A also illustrates optional bias control circuitry **1218** and associated bias control signal

1325, **1326**, and **1327**. Signals **1325**, **1326**, and **1327** may be used to bias different stages of MISO PA **1360** in certain embodiments.

[0342] Other aspects of vector power amplifier **1300**A are equivalent to those described above with respect to vector power amplifiers **1200** and **1300**.

3.3) Direct Cartesian 2-Branch Vector Power Amplifier

[0343] A Direct Cartesian 2-Branch VPA embodiment shall now be described. This name is used herein for reference purposes, and is not functionally or structurally limiting.

[0344] According to the Direct Cartesian 2-Branch VPA embodiment, a time-varying envelope signal is decomposed into two constant envelope constituent signals. The constituent signals are individually amplified equally or substantially equally, and then summed to construct an amplified version of the original time-varying envelope signal.

[0345] In one embodiment of the Direct Cartesian 2-Branch VPA embodiment, a magnitude and a phase angle of a time-varying envelope signal are calculated from in-phase and quadrature components of an input signal. Using the magnitude and phase information, in-phase and quadrature amplitude components are calculated for two constant envelope constituents of the time-varying envelope signal. The two constant envelope constituents are then generated, amplified equally or substantially equally, and summed to generate an amplified version of the original time-varying envelope signal R_{in}.

[0346] The concept of the Direct Cartesian 2-Branch VPA will now be described with reference to FIGS. **9**A and **14**.

[0347] As described and verified above with respect to FIG. **9**A, the phasor $\vec{R}'$ can be obtained by the sum of an upper phasor $\vec{U}'$ and a lower phasor $\vec{L}'$ appropriately phased to produce $\vec{R}'$. $\vec{R}'$ is calculated to be proportional to the magnitude R_{in}. Further, $\vec{U}'$ and $\vec{L}'$ can be maintained to have substantially constant magnitude. In the time domain, $\vec{U}'$ and $\vec{L}'$ represent two substantially constant envelope signals. The time domain equivalent r'(t) of $\vec{R}'$ can thus be obtained, at any time instant, by the sum of two substantially constant envelope signals.

[0348] For the case illustrated in FIG. **9**A, the phase shift of $\vec{U}'$ and $\vec{L}'$ relative to $\vec{R}'$, illustrated as angle

$$\frac{\phi}{2}$$

in FIG. **9**A, is related to the magnitude of $\vec{R}'$ as follows:

$$\frac{\phi}{2} = \cot^{-1}\left(\frac{R}{2\sqrt{1-\frac{R^2}{4}}}\right) \tag{13}$$

where R represents the normalized magnitude of phasor $\vec{R}'$.

[0349] In the time domain, it was shown that a time-varying envelope signal, r'(t)=R(t)cos(ωt) for example, can be constructed by the sum of two constant envelope signals as follows:

$$r'(t)=U'(t)+L'(t);$$

$$U'(t)=C\times\cos(\omega t)+\alpha\times\sin(\omega t);$$

$$L'(t)=C\times\cos(\omega t)-\beta\times\sin(\omega t). \tag{14}$$

where C denotes the in-phase amplitude component of phasors $\vec{U}'$ and $\vec{L}'$ and is equal or substantially equal to

$$A\times\cos\left(\frac{\phi}{2}\right)$$

(A being a constant). α and β denote the quadrature amplitude components of phasors $\vec{U}'$ and $\vec{L}'$, respectively.

[0350]

$$\alpha=\beta=A\times\sin\left(\frac{\phi}{2}\right).$$

Note that equations (14) can be modified for non-sinusoidal signals by changing the basis function from sinusoidal to the desired function.

[0351] FIG. **14** illustrates phasor $\vec{R}$ and its two constant magnitude constituent phasors $\vec{U}$ and $\vec{L}$. $\vec{R}$ is shifted by θ degrees relative to $\vec{R}'$ in FIG. **9**A. Accordingly, it can be verified that:

$$R=\vec{R}'\times e^{j\theta}=(\vec{U}'+\vec{L}')\times e^{j\theta}=\vec{U}+\vec{L};$$

$$\vec{U}=\vec{U}'\times e^{j\theta};$$

$$\vec{L}=\vec{L}'\times e^{j\theta}. \tag{15}$$

[0352] From equations (15), it can be further shown that:

$$\vec{U}=\vec{U}'\times e^{j\theta}=(C+j\alpha)\times e^{j\theta};\Rightarrow\vec{U}=(C+j\alpha)(\cos\theta+j\sin\theta)=(C\cos\theta-\alpha\sin\theta)+j(C\sin\theta+\alpha\cos\theta). \tag{16}$$

[0353] Similarly, it can be shown that:

$$\vec{L}=\vec{L}'\times e^{j\theta}=(C+j\beta)\times e^{j\theta};\Rightarrow\vec{L}=(C+j\beta)(\cos\theta+j\sin\theta)=(C\cos\theta-\beta\sin\theta)+j(C\sin\theta+\beta\cos\theta). \tag{17}$$

[0354] Equations (16) and (17) can be re-written as:

$$\vec{U}=(C\cos\theta-\alpha\sin\theta)+j(C\sin\theta+\alpha\cos\theta)=U_x+jU_y;$$

$$\vec{L}=(C\cos\theta-\beta\sin\theta)+j(C\sin\theta+\beta\cos\theta)=L_x+jL_y. \tag{18}$$

[0355] Equivalently, in the time domain:

$$U(t)=U_x\phi_1(t)+U_y\phi_2(t);$$

$$L(t)=L_x\phi_1(t)+L_y\phi_2(t); \tag{19}$$

[0356] where $\phi_1(t)$ and $\phi_2(t)$ represent an appropriately selected orthogonal basis functions.

[0357] From equations (18) and (19), it is noted that it is sufficient to calculate the values of α, β, C and $\sin(\Theta)$ and $\cos(\Theta)$) in order to determine the two constant envelope constituents of a time-varying envelope signal r(t). Further, α, β and C can be entirely determined from magnitude and phase information, equivalently I and Q components, of signal r(t).

[0358] FIG. **15** is a block diagram that conceptually illustrates an exemplary embodiment **1500** of the Direct Cartesian 2-Branch VPA embodiment. An output signal r(t) of desired power level and frequency characteristics is generated from in-phase and quadrature components according to the Direct Cartesian 2-Branch VPA embodiment.

[0359] In the example of FIG. **15**, a clock signal **1510** represents a reference signal for generating output signal r(t). Clock signal **1510** is of the same frequency as that of desired output signal r(t).

[0360] Referring to FIG. **15**, exemplary embodiment **1500** includes a first branch **1572** and a second branch **1574**. The first branch **1572** includes a vector modulator **1520** and a power amplifier (PA) **1550**. Similarly, the second branch **1574** includes a vector modulator **1530** and a power amplifier (PA) **1560**.

[0361] Still referring to FIG. **15**, clock signal **1510** is input, in parallel, into vector modulators **1520** and **1530**. In vector modulator **1520**, an in-phase version **1522** of clock signal **1510**, multiplied with U_x signal **1526**, is summed with a 90° degrees shifted version **1524** of clock signal **1510**, multiplied with U_y signal **1528**. In parallel, in vector modulator **1530**, an in-phase version **1532** of clock signal **1510**, multiplied with Lx signal **1536**, is summed with a 90° degrees shifted version **1534** of clock signal **1510**, multiplied with Ly signal **1538**. U_x signal **1526** and U_y signal **1528** correspond, respectively, to the in-phase and quadrature amplitude components of the U(t) constant envelope constituent of signal r(t) provided in equation (19). Similarly, L_x signal **1536**, and L_y signal **1538** correspond, respectively, to the in-phase and quadrature amplitude components of the L(t) constant envelope constituent of signal r(t) provided in equation (19).

[0362] Accordingly, respective output signals **1540** and **1542** of vector modulators **1520** and **1530** correspond, respectively, to the U(t) and L(t) constant envelope constituents of signal r(t) as described above in equations (19). As described above, signals **1540** and **1542** are characterized by having equal and constant or substantially equal and constant magnitude envelopes.

[0363] Referring to FIG. **15**, to generate the desired power level of output signal r(t), signals **1540** and **1542** are input into corresponding power amplifiers **1550** and **1560**.

[0364] In an embodiment, power amplifiers **1550** and **1560** apply equal or substantially equal power amplification to signals **1540** and **1542**, respectively. In an embodiment, the power amplification level of PAs **1550** and **1560** is set according to the desired power level of output signal r(t).

[0365] Amplified output signals **1562** and **1564** are substantially constant envelope signals. Accordingly, when summed together, as shown in FIG. **15**, resulting signal **1570** corresponds to the desired output signal r(t).

[0366] FIG. **15**A is another exemplary embodiment **1500**A of the Direct Cartesian 2-Branch VPA embodiment. Embodiment **1500**A represents a Multiple Input Signal Output (MISO) implementation of embodiment **1500** of FIG. **15**.

[0367] In embodiment **1500**A, constant envelope signals **1540** and **1542**, output from vector modulators **1520** and **1530**, are input into MISO PA **1580**. MISO PA **1580** is a two-input single-output power amplifier. In an embodiment, MISO PA **1580** may include various elements, such as pre-drivers, drivers, power amplifiers, and process detectors (not shown in FIG. **15**A), for example. Further, MISO PA **1580** is not limited to being a two-input PA as shown in FIG. **15**A. In other embodiments, as will be described further below with reference to FIGS. **51**A-H, PA **1580** can have any number of inputs.

[0368] Operation of the Direct Cartesian 2-Branch VPA embodiment is depicted in the process flowchart **1600** of FIG. **16**. The process begins at step **1610**, which includes receiving a baseband representation of a desired output signal. In an embodiment, the baseband representation includes I and Q components. In another embodiment, the I and Q components are RF components that are down-converted to baseband.

[0369] Step **1620** includes receiving a clock signal set according to a desired output signal frequency of the desired output signal. In the example of FIG. **15**, step **1620** is achieved by receiving clock signal **1510**.

[0370] Step **1630** includes processing the I and Q components to generate in-phase and quadrature amplitude information of first and second constant envelope constituent signals of the desired output signal. In the example of FIG. **15**, the in-phase and quadrature amplitude information is illustrated by U_x, U_y, L_x, and L_y.

[0371] Step **1640** includes processing the amplitude information and the clock signal to generate the first and second constant envelope constituent signals of the desired output signal. In an embodiment, the first and second constant envelope constituent signals are modulated according to the desired output signal frequency. In the example of FIG. **15**, step **1640** is achieved by vector modulators **1520** and **1530**, clock signal **1510**, and amplitude information signals **1526**, **1528**, **1536**, and **1538** to generate signals **1540** and **1542**.

[0372] Step **1650** includes amplifying the first and second constant envelope constituents, and summing the amplified signals to generate the desired output signal. In an embodiment, the amplification of the first and second constant envelope constituents is according to a desired power level of the desired output signal. In the example of FIG. **15**, step **1650** is achieved by PAs **1550** and **1560** amplifying respective signals **1540** and **1542** and, subsequently, by the summing of amplified signals **1562** and **1564** to generate output signal **1574**.

[0373] FIG. **17** is a block diagram that illustrates an exemplary embodiment of a vector power amplifier **1700** implementing the process flowchart **1600**. Optional components are illustrated with dashed lines, although other embodiments may have more or less optional components.

[0374] Referring to FIG. **17**, in-phase (I) and quadrature (Q) information signal **1710** is received by an I and Q Data Transfer Function module **1716**. In an embodiment, I and Q Data Transfer Function module **1716** samples signal **1710** according to a sample clock **1212**. I and Q information signal **1710** includes baseband I and Q information.

[0375] In an embodiment, I and Q Data Transfer Function module **1716** processes information signal **1710** to generate information signals **1720**, **1722**, **1724**, and **1726**. The operation of I and Q Data Transfer Function module **1716** is further described below in section 3.4.

[0376] Referring to FIG. **17**, information signal **1720** includes vector modulator **1750** quadrature amplitude information that is processed through DAC **1730** to generate signal **1740**. Information signal **1722** includes vector modulator **1750** in-phase amplitude information that is processed through DAC **1732** to generate signal **1742**. Signals **1740** and **1742** are calculated to generate a substantially constant envelope signal **1754**. With reference to FIG. **14**, for example, information signals **1720** and **1722** include the upper quadrature and in-phase components U_y and U_x, respectively.

[0377] Still referring to FIG. **17**, information signal **1726** includes vector modulator **1752** quadrature amplitude information that is processed through DAC **1736** to generate signal **1746**. Information signal **1724** includes vector modulator **1752** in-phase amplitude information that is processed through DAC **1734** to generate signal **1744**. Signals **1744** and **1746** are calculated to generate a substantially constant envelope signal **1756**. With reference to FIG. **14**, for example, information signals **1724** and **1726** include the lower in-phase and quadrature components L_x and L_y, respectively.

[0378] In the exemplary embodiment of FIG. **17**, information signals **1720**, **1722**, **1724** and **1726** are digital signals. Accordingly, each of signals **1720**, **1722**, **1724** and **1726** is fed into a corresponding digital-to-analog converter (DAC) **1730**, **1732**, **1734**, and **1736**. The resolution and sample rates of DACs **1730**, **1732**, **1734**, and **1736** are selected according to the specific desired signaling schemes. DACs **1730**, **1732**, **1734**, and **1736** are controlled by DAC clock signals **1721**, **1723**, **1725**, and **1727**, respectively. DAC clock signals **1721**, **1723**, **1725**, and **1727** may be derived from a same clock or may be independent of each other.

[0379] In other embodiments, information signals **1720**, **1722**, **1724** and **1726** are generated in analog format and no DACs are required.

[0380] Referring to FIG. **17**, DACs **1730**, **1732**, **1734**, and **1736** convert digital information signals **1720**, **1722**, **1724**, and **1726** into corresponding analog signals, and input these analog signals into optional interpolation filters **1731**, **1733**, **1735**, and **1737**, respectively. Interpolation filters **1731**, **1733**, **1735**, and **1737**, which also serve as anti-aliasing filters, shape the DACs output signals to produce the desired output waveform. Interpolation filters **1731**, **1733**, **1735**, and **1737** generate signals **1740**, **1742**, **1744**, and **1746**, respectively.

[0381] Still referring to FIG. **17**, signals **1740**, **1742**, **1744**, and **1746** are input into vector modulators **1750** and **1752**. Vector modulators **1750** and **1752** generate first and second constant envelope constituents. In the embodiment of FIG. **17**, channel clock **1714** is set according to a desired output signal frequency to thereby establish the frequency of the output signal **1770**.

[0382] Referring to FIG. **17**, vector modulator **1750** combines signal **1740**, multiplied with a 90° shifted version of channel clock signal **1714**, and signal **1742**, multiplied with a 0° shifted version of channel clock signal **1714**, to generate output signal **1754**. In parallel, vector modulator **1752** combines signal **1746**, multiplied with a 90° shifted version of channel clock signal **1714**, and signal **1744**, multiplied with a 0° shifted version of channel clock signal **1714**, to generate output signal **1756**.

[0383] Output signals **1754** and **1756** represent constant envelope signals. A sum of output signals **1754** and **1756** results in a carrier signal having the I and Q characteristics of the original baseband signal. In embodiments, to generate a desired power level at the output of vector power amplifier **1700**, signals **1754** and **1756** are amplified and then summed. In the embodiment of FIG. **17**, for example, signals **1754** and **1756** are, respectively, input into corresponding power amplifiers (PAs) **1760** and **1762**. In an embodiment, PAs **1760** and **1762** include switching power amplifiers. Autobias circuitry **1718** controls the bias of PAs **1760** and **1762**. In the embodiment of FIG. **17**, for example, autobias circuitry **1718** provides a bias voltage **1728** to PAs **1760** and **1762**.

[0384] In an embodiment, PAs **1760** and **1762** apply equal or substantially equal power amplification to respective constant envelope signals **1754** and **1756**. In an embodiment, the power amplification is set according to the desired output power level. In other embodiments of vector power amplifier **1700**, PA drivers are additionally employed to provide additional power amplification capability to the amplifier. In the embodiment of FIG. **17**, for example, PA drivers **1774** and **1776** are optionally added, respectively, between vector modulators **1750** and **1752** and subsequent PAs **1760** and **1762**.

[0385] Respective output signals **1764** and **1766** of PAs **1760** and **1762** are substantially constant envelope signals. In the embodiment of FIG. **17**, output signals **1764** and **1766** are coupled together to generate output signal **1770** of vector power amplifier **1700**. In embodiments, it is noted that the outputs of PAs **1760** and **1762** are directly coupled. Direct coupling in this manner means that there is minimal or no resistive, inductive, or capacitive isolation between the outputs of PAs **1760** and **1762**. In other words, outputs of PAs **1760** and **1762** are coupled together without intervening components. Alternatively, in an embodiment, the outputs of PAs **1760** and **1762** are coupled together indirectly through inductances and/or capacitances that result in low or minimal impedance connections, and/or connections that result in minimal isolation and minimal power loss. Alternatively, outputs of PAs **1760** and **1762** are coupled using well known combining techniques, such as Wilkinson, hybrid couplers, transformers, or known active combiners. In an embodiment, the PAs **1760** and **1762** provide integrated amplification and power combining in a single operation. In an embodiment, one or more of the power amplifiers and/or drivers described herein are implemented using multiple input, single output (MISO) power amplification techniques, examples of which are shown in FIGS. **17**A, **17**B, and **51**A-H.

[0386] Output signal **1770** represents a signal having the desired I and Q characteristics of the baseband signal and the desired output power level and frequency. In embodiments of vector power amplifier **1700**, a pull-up impedance **1778** is coupled between the output of vector power amplifier **1700** and a power supply. In other embodiments, an impedance matching network **1780** is coupled at the output of vector power amplifier **1700**. Output stage embodiments according to power amplification methods and systems of the present invention will be further described below in section 3.5.

[0387] In other embodiments of vector power amplifier **1700**, process detectors are employed to compensate for any process and/or temperature variations in circuitry of the amplifier. In the exemplary embodiment of FIG. **17**, for example, process detector **1772** is optionally added to monitor variations in PA drivers **1774** and **1776**.

[0388] FIG. **17**A is a block diagram that illustrates another exemplary embodiment **1700**A of a vector power amplifier implementing process flowchart **1600**. Optional components are illustrated with dashed lines, although other embodiments may have more or less optional components. Embodiment **1700**A illustrates a multiple-input single-output (MISO) implementation of the amplifier of FIG. **17**. In the embodiment of FIG. **17**A, constant envelope signals **1754** and **1756**, output from vector modulators **1750** and **1760**, are input into MISO PA **1790**. MISO PA **1790** is a two-input single-output power amplifier. In an embodiment, MISO PA **1790** include elements **1760**, **1762**, **1772**, **1774**, and **1776** as shown in the embodiment of FIG. **17**, or functional equivalents thereof. In another embodiment, MISO PA **1790** may include other elements, such as pre-drivers, not shown in the embodiment of FIG. **17**. Further, MISO PA **1790** is not limited to being a two-input PA as shown in FIG. **17**A. In other embodiments, as will be described further below with reference to FIGS. **51**A-H, PA **1790** can have any number of inputs.

[0389] In another embodiment of embodiment **1700**, shown as embodiment **1700**B of FIG. **17**B, optional Autobias circuitry **1218** generates separate bias control signals **1715**, **1717**, and **1719**, corresponding to Bias A, Bias B, and Bias C, respectively. Signals **1715**, **1717**, and **1719** may or may not be generated separately within Autobias circuitry **1718**, but are output separately as shown. Further, signals **1715**, **1717**, and **1719** may or may not be related as determined by the biasing required for the different stages of MISO PA **1790**.

[0390] FIG. **18** is a block diagram that illustrates another exemplary embodiment **1800** of a vector power amplifier according to the Direct Cartesian 2-Branch VPA embodiment of FIG. **16**. Optional components are illustrated with dashed lines, although other embodiments may have more or less optional components.

[0391] In the exemplary embodiment of FIG. **18**, a DAC **1820** of sufficient resolution and sample rate replaces DACs **1730**, **1732**, **1734**, and **1736** of the embodiment of FIG. **17**. DAC **1820** is controlled by a DAC clock **1814**.

[0392] DAC **1820** receives information signal **1810** from I and Q Data Transfer Function module **1716**. Information signal **1810** includes identical information content to signals **1720**, **1722**, **1724**, and **1726** in the embodiment of FIG. **17**.

[0393] DAC **1820** may output a single analog signal at a time. Accordingly, a sample-and-hold architecture may be used as shown in FIG. **18**.

[0394] In the embodiment of FIG. **18**, DAC **1820** sequentially outputs analog signals **1822**, **1824**, **1826**, and **1828** to sample-and-hold circuits **1832**, **1834**, **1836**, and **1838**, respectively. In an embodiment, DAC **1820** is of sufficient resolution and sample rate to replace DACs **1720**, **1722**, **1724**, and **1726** of the embodiment of FIG. **17**. An output selector **1812** determines which of output signals **1822**, **1824**, **1826**, and **1828** are selected for output.

[0395] DAC **1820**'s DAC clock signal **1814**, output selector signal **1812**, and sample-and-hold clocks **1830**A-D, and **1840** are controlled by a control module that can be independent or integrated into transfer function module **1716**.

[0396] In an embodiment, sample-and-hold circuits **1832**, **1834**, **1836**, and **1838** sample and hold their respective values and, according to a clock signal **1830**A-D, release the values to a second set of sample-and-hold circuits **1842**, **1844**, **1846**, and **1848**. For example, S/H **1832** release's its value to S/H **1842** according to a received clock signal **1830**A. In turn, sample-and-hold circuits **1842**, **1844**, **1846**, and **1848** hold the received analog values, and simultaneously release the values to interpolation filters **1852**, **1854**, **1856**, and **1858** according to a common clock signal **1840**.

[0397] In another embodiment, a single set of S/H circuitry that includes S/H **1832**, **1834**, **1836**, and **1838** can be employed. Accordingly, S/H circuits **1832**, **1834**, **1836**, and **1838** receive analog values from DAC **1820**, and each samples and holds its received value according to independent clocks **1830**A-D. For example, S/H **1832** is controlled by clock **1830**A, which may not be synchronized with clock **1830**B that controls S/H **1834**. For example, DAC **1820** outputs signals **1822**, **1824**, **1826**, and **1828** with appropriately selected analog values calculated by transfer function module **1716** to S/H circuits **1832**, **1834**, **1836**, and **1838** in order to compensate for the time differences between clocks **1830**A-D.

[0398] Other aspects of vector power amplifier **1800** correspond substantially to those described above with respect to vector power amplifier **1700**.

[0399] FIG. **18**A is a block diagram that illustrates another exemplary embodiment **1800**A of a vector power amplifier according to the Direct Cartesian 2-Branch VPA embodiment. Optional components are illustrated with dashed lines, although in other embodiments more or less components may be optional. Embodiment **1800**A is a Multiple Input Single Output (MISO) implementation of embodiment **1800** of FIG. **18**.

[0400] In the embodiment of FIG. **18**A, constant envelope signals **1754** and **1756**, output from vector modulators **1750** and **1752**, are input into MISO PA **1860**. MISO PA **1860** is a two-input single-output power amplifier. In an embodiment, MISO PA **1860** includes elements **1744**, **1746**, **1760**, **1762**, and **1772** as shown in the embodiment of FIG. **18**, or functional equivalents thereof. In another embodiment, MISO PA **1860** may include other elements, such as predrivers, not shown in the embodiment of FIG. **17**. Further, MISO PA **1860** is not limited to being a two-input PA as shown in FIG. **18**A. In other embodiments as will be described further below with reference to FIGS. **51**A-H, PA **1860** can have any number of inputs.

[0401] The embodiment of FIG. **18**A further illustrates two different sample and hold architectures with a single or two levels of S/H circuitry as shown. The two implementations have been described above with respect to FIG. **18**.

[0402] Other aspects of vector power amplifier **1800**A are substantially equivalent to those described above with respect to vector power amplifiers **1700** and **1800**.

3.4) I and Q Data to Vector Modulator Transfer Functions

[0403] In some of the above described embodiments, I and Q data transfer functions are provided to transform received I and Q data into amplitude information inputs for subsequent stages of vector modulation and amplification. For example, in the embodiment of FIG. **17**, I and Q Data Transfer Function module **1716** processes I and Q information signal **1710** to generate in-phase and quadrature amplitude information signals **1720**, **1722**, **1724**, and **1726** of first and second constant envelope constituents **1754** and **1756** of signal r(t). Subsequently, vector modulators **1750** and **1752**

utilize the generated amplitude information signals **1720**, **1722**, **1724**, and **1726** to create the first and second constant envelope constituent signals **1754** and **1756**. Other examples include modules **710**, **712**, and **1216** in FIGS. **7**, **8**, **12**, and **13**. These modules implement transfer functions to transform I and/or Q data into amplitude information inputs for subsequent stages of vector modulation and amplification.

[0404] According to the present invention, I and Q Data Transfer Function modules may be implemented using digital circuitry, analog circuitry, software, firmware or any combination thereof.

[0405] Several factors affect the actual implementation of a transfer function according to the present invention, and vary from embodiment to embodiment. In one aspect, the selected VPA embodiment governs the amplitude information output of the transfer function and associated module. It is apparent, for example, that I and Q Data Transfer Function module **1216** of the CPCP 2-Branch VPA embodiment **1200** differs in output than I and Q Data Transfer Function module **1716** of the Direct Cartesian 2-Branch VPA embodiment **1700**.

[0406] In another aspect, the complexity of the transfer function varies according to the desired modulation scheme (s) that need to be supported by the VPA implementation. For example, the sample clock, the DAC sample rate, and the DAC resolution are selected in accordance with the appropriate transfer function to construct the desired output waveform(s).

[0407] According to the present invention, transfer function embodiments may be designed to support one or more VPA embodiments with the ability to switch between the supported embodiments as desired. Further, transfer function embodiments and associated modules can be designed to accommodate a plurality of modulation schemes. A person skilled in the art will appreciate, for example, that embodiments of the present invention may be designed to support a plurality of modulation schemes (individually or in combination) including, but not limited to, BPSK, QPSK, OQPSK, DPSK, CDMA, WCDMA, W-CDMA, GSM, EDGE, MPSK, MQAM, MSK, CPSK, PM, FM, OFDM, and multi-tone signals. In an embodiment, the modulation scheme(s) may be configurable and/or programmable via the transfer function module.

3.4.1) Cartesian 4-Branch VPA Transfer Function

[0408] FIG. **19** is a process flowchart **1900** that illustrates an example I and Q transfer function embodiment according to the Cartesian 4-Branch VPA embodiment. The process begins at step **1910**, which includes receiving an in-phase data component and a quadrature data component. In the Cartesian 4-Branch VPA embodiment of FIG. **7**A, for example, this is illustrated by I Data Transfer Function module **710** receiving I information signal **702**, and Q Data Transfer Function module **712** receiving Q information signal **704**. It is noted that, in the embodiment of FIG. **7**A, I and Q Data Transfer Function modules **710** and **712** are illustrated as separate components. In implementation, however, I and Q Data Transfer Function modules **710** and **712** may be separate or combined into a single module.

[0409] Step **1920** includes calculating a phase shift angle between first and second substantially equal and constant envelope constituents of the I component. In parallel, step **1920** also includes calculating a phase shift angle between first and second substantially equal and constant envelope constituents of the Q component. As described above, the first and second constant envelope constituents of the I components are appropriately phased relative to the I component. Similarly, the first and second constant envelope constituents of the Q components are appropriately phased relative to the Q component. In the embodiment of FIG. **7**A, for example, step **1920** is performed by I and Q Data Transfer Function modules **710** and **712**.

[0410] Step **1930** includes calculating in-phase and quadrature amplitude information associated with the first and second constant envelope constituents of the I component. In parallel, step **1930** includes calculating in-phase and quadrature amplitude information associated with the first and second constant envelope constituents of the Q component. In the embodiment of FIG. **7**A, for example, step **1930** is performed by and I and Q Data Transfer Function modules **710** and **712**.

[0411] Step **1940** includes outputting the calculated amplitude information to a subsequent vector modulation stage. In the embodiment of FIG. **7**A, for example, I and Q Transfer Function modules **710** and **712** output amplitude information signals **722**, **724**, **726**, and **728** to vector modulators **760**, **762**, **764**, and **766** through DACs **730**, **732**, **734**, and **736**.

[0412] FIG. **20** is a block diagram that illustrates an exemplary embodiment **2000** of a transfer function module, such as transfer function modules **710** and **712** of FIG. **7**A, implementing the process flowchart **1900**. In the example of FIG. **20**, transfer function module **2000** receives I and Q data signals **2010** and **2012**. In an embodiment, I and Q data signals **2010** and **2012** represent I and Q data components of a baseband signal, such as signals **702** and **704** in FIG. **7**A.

[0413] Referring to FIG. **20**, in an embodiment, transfer function module **2000** samples I and Q data signals **2010** and **2012** according to a sampling clock **2014**. Sampled I and Q data signals are received by components **2020** and **2022**, respectively, of transfer function module **2000**. Components **2020** and **2022** measure, respectively, the magnitudes of the sampled I and Q data signals. In an embodiment, components **2020** and **2022** are magnitude detectors.

[0414] Components **2020** and **2022** output the measured I and Q magnitude information to components **2030** and **2032**, respectively, of transfer function module **2000**. In an embodiment, the measured I and Q magnitude information is in the form of digital signals. Based on the I magnitude information, component **2030** calculates a phase shift angle ϕ_I between first and second equal and constant or substantially equal and constant envelope constituents of the sampled I signal. Similarly, based on the Q magnitude information, component **2032** calculates phase shift angle ϕ_Q between a first and second equal and constant or substantially equal and constant envelope constituents of the sampled Q signal. This operation shall now be further described.

[0415] In the embodiment of FIG. **20**, ϕ_I and ϕ_Q are illustrated as functions $f(|\vec{I}|)$ and $f(|\vec{Q}|)$ of the I and Q magnitude signals. In embodiments, functions $f(|\vec{I}|)$ and $f(|\vec{Q}|)$ are set according to the relative magnitudes of the baseband I and Q signals respectively. $f(|\vec{I}|)$ and $f(|\vec{Q}|)$ according to embodiments of the present invention will be further described below in section 3.4.4.

[0416] Referring to FIG. **20**, components **2030** and **2032** output the calculated phase shift information to components **2040** and **2042**, respectively. Based on phase shift angle ϕ_I, component **2040** calculates in-phase and quadrature amplitude information of the first and second constant envelope constituents of the sampled I signal. Similarly, based on phase shift angle ϕ_Q, component **2042** calculates in-phase and quadrature amplitude information of the first and second constant envelope constituents of the sampled Q signal. Due to symmetry, in embodiments of the invention, calculation is required for 4 values only. In the example of FIG. **20**, the values are illustrated as $\mathrm{sgn}(I)\times I_{UX}$, I_{UY}, Q_{UX}, and $\mathrm{sgn}(Q)\times Q_{UY}$, as provided in FIG. **5**.

[0417] Components **2040** and **2042** output the calculated amplitude information to subsequent stages of the vector power amplifier. In embodiments, each of the four calculated values is output separately to a digital-to-analog converter. As shown in the embodiment of FIG. **7**A for example, signals **722**, **724**, **726**, and **728** are output separately to DACs **730**, **732**, **734**, and **736**, respectively. In other embodiments, signals **722**, **724**, **726**, and **728** are output into a single DAC as shown in FIGS. **800**A and **800**B.

3.4.2) CPCP 2-Branch VPA Transfer Function

[0418] FIG. **21** is a process flowchart **2100** that illustrates an example I and Q transfer function embodiment according to the CPCP 2-Branch VPA embodiment. The process begins at step **2110**, which includes receiving in-phase (I) and quadrature (Q) data components of a baseband signal. In the CPCP 2-Branch VPA embodiment of FIG. **12**, for example, this is illustrated by I and Q Data Transfer Function module **1216** receiving I and Q information signal **1210**.

[0419] Step **2120** includes determining the magnitudes $|I|$ and $|Q|$ of the received I and Q data components.

[0420] Step **2130** includes calculating a magnitude $|R|$ of the baseband signal based on the measured $|I|$ and $|Q|$ magnitudes. In an embodiment, $|R|$ is such that $|R|^2=|I|^2+|Q|^2$. In the embodiment of FIG. **12**, for example, steps **2120** and **2130** are performed by I and Q Data Transfer Function module **1216** based on received information signal **1210**.

[0421] Step **2140** includes normalizing the measured $|I|$ and $|Q|$ magnitudes. In an embodiment, $|I|$ and $|Q|$ are normalized to generate an Iclk_phase and Q_{clk}_phase signals (as shown in FIG. **10**) such that $|I_{clk_phase}|^2+|Q_{clk_phase}|^2=$constant. In the embodiment of FIG. **12**, for example, step **2140** is performed by I and Q Data Transfer Function module **1216** based on received information signal **1210**.

[0422] Step **2150** includes calculating in-phase and quadrature amplitude information associated with first and second constant envelope constituents. In the embodiment of FIG. **12**, for example, step **2150** is performed by I and Q Data Transfer Function module **1216** based on the envelope magnitude $|R|$.

[0423] Step **2160** includes outputting the generated Iclk_phase and Qclk_phase (from step **2140**) and the calculated amplitude information (from step **2150**) to appropriate vector modulators. In the embodiment of FIG. **12**, for example, I and Q Data Transfer Function module **1216** output information signals **1220**, **1222**, **1224**, and **1226** to vector modulators **1238**, **1260**, and **1262** through DACs **1230**, **1232**, **1234**, and **1236**.

[0424] FIG. **22** is a block diagram that illustrates an exemplary embodiment **2200** of a transfer function module (such as module **1216** of FIG. **12**) implementing the process flowchart **2100**. In the example of FIG. **22**, transfer function module **2200** receives I and Q data signal **2210**. In an embodiment, I and Q data signal **2210** includes I and Q components of a baseband signal, such as signal **1210** in the embodiment of FIG. **12**, for example.

[0425] In an embodiment, transfer function module **2200** samples I and Q data signal **2210** according to a sampling clock **2212**. Sampled I and Q data signals are received by component **2220** of transfer function module **2200**. Component **2220** measures the magnitudes $|\vec{I}|$ and $|\vec{Q}|$ of the sampled I and Q data signals.

[0426] Based on the measured $|\vec{I}|$ and $|\vec{Q}|$ magnitudes, component **2230** calculates the magnitude $|R|$ of the baseband signal. In an embodiment, $|\vec{R}|$ is such that $|\vec{R}|^2=|\vec{I}|^2+|\vec{Q}|^2$.

[0427] In parallel, component **2240** normalizes the measured $|\vec{I}|$ and $|\vec{Q}|$ magnitudes. In an embodiment, $|\vec{I}|$ and $|\vec{Q}|$ are normalized to generate Iclk_phase and Qclk_phase signals such that $|\text{Iclk_phase}|^2+|\text{Qclk_phase}|^2=$constant, where |Iclk_phase| and |Qclk_phase| represent normalized magnitudes of $|\vec{I}|$ and $|\vec{Q}|$. Typically, given that the constant has a value A, the measured $|\vec{I}|$ and $|\vec{I}|$ magnitudes are both divided by the quantity

$$\frac{A}{\sqrt{|\vec{I}|^2+|\vec{Q}|^2}}$$

[0428] Component **2250** receives the calculated $|\vec{R}|$ magnitude from component **2230**, and based on it calculates a phase shift angle ϕ between first and second constant envelope constituents. Using the calculated phase shift angle ϕ, component **2050** then calculates in-phase and quadrature amplitude information associated with the first and second constant envelope constituents.

[0429] In the embodiment of FIG. **22**, the phase shift angle ϕ is illustrated as a function $f(|\vec{R}|)$ of the calculated magnitude $|\vec{R}|$.

[0430] Referring to FIG. **22**, components **2240** and **2250** output the normalized |Iclk_phase| and |Qclk_phase| magnitude information and the calculated amplitude information to DAC's for input into the appropriate vector modulators. In embodiments, the output values are separately output to digital-to-analog converters. As shown in the embodiment of FIG. **12**, for example, signals **1220**, **1222**, **1224**, and **1226** are output separately to DACs **1230**, **1232**, **1234**, and **1236**, respectively. In other embodiments, signals **1220**, **1222**, **1224**, and **1226** are output into a single DAC as shown in FIGS. **13** and **13**A.

3.4.3) Direct Cartesian 2-Branch Transfer Function

[0431] FIG. **23** is a process flowchart **2300** that illustrates an example I and Q transfer function embodiment according to the Direct Cartesian 2-Branch VPA embodiment. The process begins at step **2310**, which includes receiving in-phase (I) and quadrature (Q) data components of a baseband signal. In the Direct Cartesian 2-Branch VPA embodiment of

FIG. **17**, for example, this is illustrated by I and Q Data Transfer Function module **1716** receiving I and Q information signal **1710**.

[0432] Step **2320** includes determining the magnitudes |I| and |Q| of the received I and Q data components.

[0433] Step **2330** includes calculating a magnitude |R| of the baseband signal based on the measured |I| and |Q| magnitudes. In an embodiment, |R| is such that $|R|^2=|I|^2+|Q|^2$. In the embodiment of FIG. **17**, for example, steps **2320** and **2330** are performed by I and Q Data Transfer Function module **1716** based on received information signal **1710**.

[0434] Step **2340** includes calculating a phase shift angle θ of the baseband signal based on the measured |I| and |Q| magnitudes. In an embodiment, θ is such that

$$\theta=\tan^{-1}\left(\frac{|Q|}{|I|}\right),$$

and wherein the sign of I and Q determine the quadrant of θ. In the embodiment of FIG. **17**, for example, step **2340** is performed by I and Q Data Transfer Function module **1216** based on I and Q data components received in information signal **1210**.

[0435] Step **2350** includes calculating in-phase and quadrature amplitude information associated with a first and second constant envelope constituents of the baseband signal. In the embodiment of FIG. **17**, for example, step **2350** is performed by I and Q Data Transfer Function module **1716** based on previously calculated magnitude |R| and phase shift angle θ.

[0436] Step **2360** includes outputting the calculated amplitude information to DAC's for input into the appropriate vector modulators. In the embodiment of FIG. **17**, for example, I and Q Data Transfer Function module **1716** output information signals **1720**, **1722**, **1724**, and **1726** to vector modulators **1750** and **1752** through DACs **1730**, **1732**, **1734**, and **1736**. In other embodiments, signals **1720**, **1722**, **1724**, and **1726** are output into a single DAC as shown in FIGS. **18** and **18**A.

[0437] FIG. **24** is a block diagram that illustrates an exemplary embodiment **2400** of a transfer function module implementing the process flowchart **2300**. In the example of FIG. **24**, transfer function module **2400** (such as transfer function module **1716**) receives I and Q data signal **2410**, such as signal **1710** in FIG. **17**. In an embodiment, I and Q data signal **2410** includes I and Q data components of a baseband signal.

[0438] In an embodiment, transfer function module **2400** samples I and Q data signal **2410** according to a sampling clock **2412**. Sampled I and Q data signals are received by component **2420** of transfer function module **2200**. Component **2420** measures the magnitudes $|\vec{I}|$ and $|\vec{Q}|$ of the sampled I and Q data signals.

[0439] Based on the measured $|\vec{I}|$ and $|\vec{Q}|$ magnitudes, component **2430** calculates the magnitude $|\vec{R}|$. In an embodiment, $|\vec{R}|$ is such that $|\vec{R}|^2=|\vec{I}|^2+|\vec{Q}|^2$.

[0440] In parallel, component **2240** calculates the phase shift angle θ of the baseband signal. In an embodiment, θ is such that

$$\theta=\tan^{-1}\left(\frac{|\vec{Q}|}{|\vec{I}|}\right),$$

where the sign of I and Q determine the quadrant of θ.

[0441] Component **2450** receives the calculated $|\vec{R}|$ magnitude from component **2430**, and based on it calculates a phase shift angle ϕ between first and second constant envelope constituent signals. In the embodiment of FIG. **24**, the phase shift angle ϕ is illustrated as a function $f_3|\vec{R}|)$ of the calculated magnitude $|\vec{R}|$. This is further described in section 3.4.4.

[0442] In parallel, component **2450** receives the calculated phase shift angle θ from component **2440**. As functions of ϕ and θ, component **2450** then calculates in-phase and quadrature amplitude information for the vector modulator inputs that generate the first and second constant envelope constituents. In an embodiment, the in-phase and quadrature amplitude information supplied to the vector modulators are according to the equations provided in (18).

[0443] Component **2450** outputs the calculated amplitude information to subsequent stages of the vector power amplifier. In embodiments, the output values are separately output to digital-to-analog converters. As shown in the embodiment of FIG. **17**, for example, signals **1720**, **1722**, **1724**, and **1726** are output separately to DACs **1730**, **1732**, **1734**, and **1736**, respectively. In other embodiments, signals **1720**, **1722**, **1724**, and **1726** are output into a single DAC as shown in FIGS. **18** and **18**A.

3.4.4) Magnitude to Phase Shift Transform

[0444] Embodiments of f(|I|), f(|Q|) of FIG. **20** and f(|R|) of FIGS. **22** and **24** shall now be further described.

[0445] According to the present invention, any periodic waveform that can be represented by a Fourier series and a Fourier transform can be decomposed into two or more constant envelope signals.

[0446] Below are provided two examples for sinusoidal and square waveforms.

3.4.4.1) Magnitude to Phase Shift Transform for Sinusoidal Signals

[0447] Consider a time-varying complex envelope sinusoidal signal r(t). In the time domain, it can be represented as:

$$r(t)=R(t)\sin(\omega t+\delta(t)) \tag{20}$$

where R(t) represents the signal's envelope magnitude at time t, δ(t) represents the signal's phase shift angle at time t, and ω represents the signal's frequency in radians per second.

[0448] It can be verified that, at any time instant t, signal r(t) can be obtained by the sum of two appropriately phased equal and constant or substantially equal and constant envelope signals. In other words, it can be shown that:

$$R(t)\sin(\omega t+\delta(t))=A\ \sin(\omega t)+A\ \sin(\omega t+\phi(t)) \tag{21}$$

for an appropriately chosen phase shift angle ϕ(t) between the two constant envelope signals. The phase shift angle ϕ(t) will be derived as a function of R(t) in the description below. This is equivalent to the magnitude to phase shift transform for sinusoidal signals.

[0449] Using a sine trigonometric identity, equation (21) can be re-written as:

$$R(t)\sin(\omega t+\delta(t))=A\ \sin(\omega t)+A\ \sin(\omega t))\cos\ \phi t)+\mathrm{A}\ \sin(\phi(t))\cos\ \omega t;\ \Rightarrow R(t)\sin(\omega t+\delta(t))=A\ \sin(\phi(t))\cos\ \omega t+A(1+\cos\ \phi(t))\sin\ \omega t. \tag{22}$$

[0450] Note, from equation (22), that signal r(t) is written as a sum of an in-phase component and a quadrature component. Accordingly, the envelope magnitude R(t) can be written as:

$$R(t)=\sqrt{(A\sin(\phi(t)))^2+(A(1+\cos(\phi(t))))^2};\ \Rightarrow R(t)=\sqrt{2A(A+\cos(\phi(t)))}. \tag{23}$$

[0451] Equation (23) relates the envelope magnitude R(t) of signal r(t) to the phase shift angle φ(t) between two constant envelope constituents of signal r(t). The constant envelope constituents have equal or substantially equal envelope magnitude A, which is typically normalized to 1.

[0452] Inversely, from equation (23), the phase shift angle φ(t) can be written as a function of R(t) as follows:

$$\phi(t)=\arccos\left(\frac{R(t)^2}{2A^2}-1\right). \tag{24}$$

[0453] Equation (24) represents the magnitude to phase shift transform for the case of sinusoidal signals, and is illustrated in FIG. **26**.

3.4.4.2) Magnitude to Phase Shift Transform for Square Wave Signals:

[0454] FIG. **28** illustrates a combination of two constant envelope square wave signals according to embodiments of the present invention. In FIG. **28**, signals **2810** and **2820** are constant envelope signals having a period T, a duty cycle γT (0<γ<1), and envelope magnitudes A1 and A2, respectively.

[0455] Signal **2830** results from combining signals **2810** and **2820**. According to embodiments of the present invention, signal **2830** will have a magnitude equal or substantially equal to a product of signals **2810** and **2820**. In other words, signal **2830** will have a magnitude of zero whenever either of signals **2810** or **2820** has a magnitude of zero, and a non-zero magnitude when both signals **2810** and **2820** have non-zero magnitudes.

[0456] Further, signal **2830** represents a pulse-width-modulated signal. In other words, the envelope magnitude of signal **2830** is determined according to the pulse width of signal **2830** over one period of the signal. More specifically, the envelope magnitude of signal **2830** is equal or substantially to the area under the curve of signal **2830**.

[0457] Referring to FIG. **28**, signals **2810** and **2820** are shown time-shifted relative to each other by a time shift t'. Equivalently, signals **2810** and **2820** are phase-shifted relative to each other by a phase shift

angles $\phi=\left(\frac{t'}{T}\right)\times 2\pi$ radians.

[0458] Still referring to FIG. **28**, note that the envelope magnitude R of signal **2830**, in FIG. **28**, is given by:

$$R=A_1\times A_2\times(\gamma T-t') \tag{25}$$

[0459] Accordingly, it can be deduced that φ is related to R according to:

$$\phi=\left[\gamma-\frac{R}{T(A_1A_2)}\right]\times(2\pi). \tag{26}$$

[0460] Note, from equation (26), that R is at a maximum of γA1A2 when φ=0. In other words, the envelope magnitude is at a maximum when the two constant envelope signals are in-phase with each other.

[0461] In typical implementations, signals **2810** and **2820** are normalized and have equal or substantially equal envelope magnitude of 1. Further, signals **2810** and **2820** typically have a duty cycle of 0.5. Accordingly, equation (26) reduces to:

$$\phi=\left[0.5-\frac{R}{T}\right]\times(2\pi). \tag{27}$$

[0462] Equation (27) illustrates the magnitude to phase shift transform for the case of normalized and equal or substantially equal envelope magnitude square wave signals. Equation (27) is illustrated in FIG. **26**.

3.4.5) Waveform Distortion Compensation

[0463] In certain embodiments, magnitude to phase shift transforms may not be implemented exactly as theoretically or practically desired. In fact, several factors may exist that require adjustment or tuning of the derived magnitude to phase shift transform for optimal (or at least improved) operation. In practice, phase and amplitude errors may exist in the vector modulation circuitry, gain and phase imbalances can occur in the vector power amplifier branches, and distortion may exist in the MISO amplifier itself including but not limited to errors introduced by directly combining at a single circuit node transistor outputs within the MISO amplifier described herein. Each of these factors either singularly or in combination will contribute to output waveform distortions that result in deviations from the desired output signal r(t). When output waveform distortion exceeds system design requirements, waveform distortion compensation may be required.

[0464] FIG. **25** illustrates the effect of waveform distortion on a signal using phasor signal representation. In FIG. **25**, $\vec{R}$ represents a phasor representation of a desired signal r(t). In the example of FIG. **25**, waveform distortion can cause the actual output phasor to vary from r(t) anywhere within the phasor error region. An exemplary phasor error region is illustrated in FIG. **25**, and is equal or substantially equal to the maximum error vector magnitude. Phasors $\vec{R}_1$ and $\vec{R}_2$ represent examples of potential output phasors that deviate from the desired r(t).

[0465] According to embodiments of the present invention, waveform distortions can be measured, calculated, or estimated during the manufacture of the system and/or in real time or non-real time operation. FIG. **54**A and FIG. **55** are examples of methods that can be used for phasor error measurement and correction. These waveform distortions can be compensated for or reduced at various points in the system. For example, a phase error between the branch amplifiers can be adjusted by applying an analog voltage offset to the vector modulation circuitry, within the transfer function, and/or using real time or non-real time feedback techniques as shown in the example system illustrated in FIGS. **58**, **59** and **60**. Similarly, branch amplification imbalances can be adjusted by applying an analog voltage offset to the vector modulation circuitry, within the transfer function, and/or using real time or non-real time feedback techniques as shown in FIGS. **58**, **59** and **60**. In the system illustrated in FIGS. **58**, **59** and **60**, for example, waveform distortion adjustment is performed, as illustrated in FIG. **60**, using Differential Branch Amplitude Measurement Circuitry **6024** and Differential Branch Phase Measurement Circuitry **6026**, which provide a Differential Branch Amplitude signal **5950** and a Differential Branch Phase signal **5948**, respectively. These signals are input into an A/D Converter **5732** by input signal selector **5946**, with the values generated by AID converter **5732** being input into Digital Control Module **5602**. Digital Control Module **5602** uses the values generated by A/D converter **5732** to calculate adjusted or offset values to provide control voltages for phase adjustments to Vector modulation circuitry **5922**, **5924**, **5926**, and **5928** and control voltages for amplitude adjustments to Gain Balance control circuitry **6016**. In FIG. **58**, these control voltages are illustrated using Gain Balance Control signal **5749** and Phase Balance Control signal **5751**. The feedback approach described above also compensates for process variations, temperature variations, IC package variations, and circuit board variations by ensuring the system amplitude and phase errors remain with a specified tolerance. Additional example feedback and feedforward error measurement and compensation techniques are further described in section 4.1.2.

[0466] In other embodiments, the measured, calculated, or estimated waveform distortions are compensated for at the transfer function stage of the power amplifier. In this approach, the transfer function is designed to factor in and correct the measured, calculated, and/or estimated waveform distortions. FIG. **78** illustrates a mathematical derivation of the magnitude to phase shift transform in the presence of amplitude and phase errors in branches of the VPA. Equation (28) in FIG. **78** takes into account both phase and amplitude errors in an exemplary embodiment. Note that $R^*\sin(\acute{\omega}^*t+\delta)$ in FIG. **78** can be representative of either $\vec{R_1}$ or $\vec{R_2}$ in FIG. **25**, for example. Equation (28) assumes that amplitudes A**1** and A**2** of the VPA branches can be different and that each branch can contain a respective phase error ϕe**1**(t) and ϕe**2**(t). For reference purposes, in a theoretically perfect system, A**1**=A**2** and ϕe**1**(t)=ϕe**2**(t)=0. δ(t) is adjusted by quadrant based on the sign value of the input vectors I(t) and Q(t). As such, with no amplitude or phase errors, the phasor corresponding to $R^*\sin(\acute{\omega}^*t+\delta)$ is aligned with the desired phasor $\vec{R}$ in FIG. **25**.

[0467] In some embodiments, in practice, amplitude and phase components of the phasor corresponding to $R^*\sin(\acute{\omega}^*t+\delta)$ are compared to the desired phasor $\vec{R}$ to generate system amplitude and phase error deviations. These amplitude and phase error deviations from the desired phasor $\vec{R}$, as shown in FIG. **25**, can be accounted for in the system transfer function. In an embodiment, A**1** and A**2** can be substantially equalized and ϕe**1**(t) and ϕe**2**(t) can be minimized by properly adjusting the control inputs to the vector modulation circuitry. In an embodiment, as illustrated in FIG. **57**, this is performed by the digital control module, which provides, using digital-to-analog converters DAC_**01**, DAC_**02**, DAC_**03**, and DAC_**04**, control inputs to the vector modulation circuitry.

[0468] Accordingly, given the fact that equations such as equation (28) can be used to calculate the resultant phasor at any instant in time based on the values of A**1** and A**2** and ϕe**1**(t) and ϕe**2**(t), transfer function modification(s) can be made to compensate for the system errors, and such transfer function modification(s) will be apparent to persons skilled in the relevant art(s) based on the teachings contained herein. Exemplary methods for generating error tables and/or mathematical functions to compensate for system errors are described in Section 4.1.2. It will be apparent to persons skilled in the relevant art(s) that these waveform distortion correction and compensation techniques can be implemented in either the digital or the analog domains, and implementation of such techniques will be apparent to persons skilled in the relevant art(s) based on the teachings contained herein.

3.5) Output Stage

[0469] An aspect of embodiments of the present invention lies in summing constituent signals at the output stage of a vector power amplifier (VPA). This is shown, for example, in FIG. **7** where the outputs of PAs **770**, **772**, **774**, and **776** are summed. This is similarly shown in FIGS. **8**, **12**, **13**, **17**, and **18**, for example. Various embodiments for combining the outputs of VPAs are described herein. While the following is described in the context of VPAs, it should be understood that the following teachings generally apply to coupling or summing the outputs of any active devices in any application.

[0470] FIG. **29** illustrates a vector power amplifier output stage embodiment **2900** according to an embodiment of the present invention. Output stage **2900** includes a plurality of vector modulator signals **2910**-{**1**, . . . , n} being input into a plurality of corresponding power amplifiers (PAs) **2920**-{**1**, . . . , n}. As described above, signals **2910**-{**1**, . . . , n} represent constituent signals of a desired output signal of the vector power amplifier.

[0471] In the example of FIG. **29**, PAs **2910**-{**1**, . . . , n} equally amplify or substantially equally amplify input signals **2910**-{**1**, . . . , n} to generate amplified output signals **2930**-{ **1**, . . . , n}. Amplified output signals **2930**-{**1**, . . . , n} are coupled together directly at summing node **2940**. According to this example embodiment of the present invention, summing node **2940** includes no coupling or isolating element, such as a power combiner, for example. In the embodiment of FIG. **29**, summing node **2940** is a zero-impedance (or near-zero impedance) conducting wire. Accordingly, unlike in conventional systems that employ combining elements, the combining of output signals according to this embodiment of the present invention incurs minimal power loss.

[0472] In another aspect, output stage embodiments of the present invention can be implemented using multiple-input single-output (MISO) power amplifiers.

[0473] In another aspect, output stage embodiments of the present invention can be controlled to increase the power efficiency of the amplifier by controlling the output stage current according to the desired output power level.

[0474] In what follows, various output stage embodiments according to VPA embodiments of the present invention are provided in section 3.5.1. In section 3.5.2, embodiments of output stage current shaping functions, for increasing the power efficiency of certain VPA embodiments of the present invention, are presented. Section 3.5.3 describes embodiments of output stage protection techniques that may be utilized for certain output stage embodiments of the present invention.

3.5.1) Output Stage Embodiments

[0475] FIG. **30** is a block diagram that illustrates a power amplifier (PA) output stage embodiment **3000** according to an embodiment of the present invention. Output stage embodiment **3000** includes a plurality of PA branches **3005**-{**1**, . . . , n}. Signals **3010**-{**1**, . . . , n} incoming from respective vector modulators represent inputs for output stage **3000**. According to this embodiment of the present invention, signals **3010**-{**1**, . . . , n} represent equal and constant or substantially equal and constant envelope constituent signals of a desired output signal of the power amplifier.

[0476] PA branches **3005**-{**1**, . . . , n} apply equal or substantially equal power amplification to respective signals **3010**-{**1**, . . . , n}. In an embodiment, the power amplification level through PA branches **3005**-{**1**, . . . , n} is set according to a power level requirement of the desired output signal.

[0477] In the embodiment of FIG. **30**, PA branches **3005**-{**1**, . . . , n} each includes a power amplifier **3040**-{**1**, . . . , n}. In other embodiments, drivers **3030**-{**1**, . . . , n} and pre-drivers **3020**-{**1**, . . . , n}, as illustrated in FIG. **30**, may also be added in a PA branch prior to the power amplifier element. In embodiments, drivers and pre-drivers are employed whenever a required output power level may not be achieved in a single amplifying stage.

[0478] To generate the desired output signal, outputs of PA branches **3005**-{**1**, . . . , n} are coupled directly at summing node **3050**. Summing node **3050** provides little or no isolation between the coupled outputs. Further, summing node **3050** represents a relatively lossless summing node. Accordingly, minimal power loss is incurred in summing the outputs of PAs **3040**-{**1**, . . . , n}.

[0479] Output signal **3060** represents the desired output signal of output stage **3000**. In the embodiment of FIG. **30**, output signal **3060** is measured across a load impedance **3070**.

[0480] FIG. **31** is a block diagram that illustrates another power amplifier (PA) output stage embodiment **3100** according to the present invention. Similar to the embodiment of FIG. **30**, output stage **3100** includes a plurality of PA branches **3105**-{**1**, . . . , n}. Each of PA branches **3105**-{**1**, . . . , n} may include multiple power amplification stages represented by a pre-driver **3020**-{**1**, . . . , n}, driver **3030**-{**1**, . . . , n}, and power amplifier **3040**-{**1**, . . . , n}. Output stage embodiment **3100** further includes pull-up impedances coupled at the output of each power amplification stage to provide biasing of that stage. For example, pull-up impedances **3125**-{**1**, . . . , n} and **3135**-{**1** , . . . , n}, respectively, couple the pre-driver and driver stage outputs to power supply or independent bias power supplies. Similarly, pull-up impedance **3145** couples the PA stage outputs to the power supply or an independent bias power supply. According to this embodiment of the present invention, pull-up impedances represent optional components that may affect the efficiency but not necessarily the operation of the output stage embodiment.

[0481] FIG. **32** is a block diagram that illustrates another power amplifier (PA) output stage embodiment **3200** according to the present invention. Similar to the embodiment of FIG. **30**, output stage **3200** includes a plurality of PA branches **3205**-{**1**, . . . , n}. Each of PA branches **3205**-{**1**, . . . , n} may include multiple power amplification stages represented by a pre-driver **3020**-{**1**, . . . , n}, driver **3030**-{**1**, . . . , n}, and power amplifier **3040**-{**1**, . . . , n}. Output stage embodiment **3200** also includes pull-up impedances coupled at the output of each power amplification stage to achieve a proper biasing of that stage. Further, output stage embodiment **3200** includes matching impedances coupled at the outputs of each power amplification stage to maximize power transfer from that stage. For example, matching impedances **3210**-{**1**, . . . , n} and **3220**-{**1**, . . . , n}, are respectively coupled to the pre-driver and driver stage outputs. Similarly, matching impedance **3240** is coupled at the PA stage output. Note that matching impedance **3240** is coupled to the PA output stage subsequent to summing node **3250**.

[0482] In the above-described embodiments of FIGS. **30**-**32**, the PA stage outputs are combined by direct coupling at a summing node. For example, in the embodiment of FIG. **30**, outputs of PA branches **3005**-{**1**, . . . , n} are coupled together at summing node **3050**. Summing node **3050** is a near zero-impedance conducting wire that provides minimal isolation between the coupled outputs. Similar output stage coupling is shown in FIGS. **31** and **32**. It is noted that in certain embodiments of the present invention, output coupling, as shown in the embodiments of FIGS. **30**-**32** or embodiments subsequently described below, may utilize certain output stage protection measures. These protection measures may be implemented at different stages of the PA branch. Further, the type of protection measures needed may be PA implementation-specific. A further discussion of output stage protection according to an embodiment of the present invention is provided in section 3.5.3.

[0483] FIG. **33** is a block diagram that illustrates another power amplifier (PA) output stage embodiment **3300** according to the present invention. Similar to the embodiment of FIG. **30**, output stage **3300** includes a plurality of PA branches **3305**-{**1**, . . . , n}. Each of PA branches **3305**-{**1**, . . . , n} may include multiple power amplification stages represented by a pre-driver **3020**-{**1**, . . . , n}, driver **3030**-{**1**, . . . , n}, and power amplifier **3040**-{**1**, . . . , n}. Output stage embodiment **3300** may also include pull-up impedances **3125**-{**1**, . . . , n}, **3135**-{**1**, . . . , n}, and **3145** coupled at the output of each power amplification stage to achieve a proper biasing of that stage. Additionally, output stage embodiment **3300** may include matching impedances **3210**-{**1**, . . . , n}, **3220**-{**1**, . . . , n}, and **3240** coupled at the output of each power amplification stage to maximize power transfer from that stage. Further, output stage embodiment **3300** receives an autobias signal **3310**, from an Autobias module **3340**, coupled at the PA stage input of each PA branch **3305**-{**1**, . . . , n}. Autobias module **3340** controls the bias of PAs **3040**-{**1**, . . . , n}. In an embodiment, autobias signal **3340** controls the amount of current flow through the PA stage according to a desired output power level and signal envelope of the output waveform. A further description of the operation of autobias signal and the autobias module is provided below in section 3.5.2.

[0484] FIG. **34** is a block diagram that illustrates another power amplifier (PA) output stage embodiment **3400** according to the present invention. Similar to the embodiment of FIG. **30**, output stage **3400** includes a plurality of PA branches **3405**-{**1**, . . . , n}. Each of PA branches **3405**-{**1**, . . . , n} may include multiple power amplification stages represented by a pre-driver **3020**-{**1**, . . . , n}, driver **3030**-{**1**, . . . , n}, and power amplifier **3040**-{**1**, . . . , n}. Output stage embodiment **3400** may also include pull-impedances **3125**-{**1**, . . . , n}, **3135**-{**1**, . . . , n}, and **3145** coupled at the output of each power amplification stage to achieve desired biasing of that stage. Additionally, output stage embodiment **3400** may include matching impedances **3210**-{**1**, . . . , n}, **3220**-{**1**, . . . , n}, and **3240** coupled at the output of each power amplification stage to maximize power transfer from that stage. Further, output stage embodiment **3400** includes a plurality of harmonic control circuit networks **3410**-{**1**, . . . , n} coupled at the PA stage input of each PA branch {**1**, . . . , n}. Harmonic control circuit networks **3410**-{**1**, . . . , n} may include a plurality of resistance, capacitance, and/or inductive elements and/or active devices coupled in series or in parallel. According to an embodiment of the present invention, harmonic control circuit networks **3410**-{**1**, . . . , n} provide harmonic control functions for controlling the output frequency spectrum of the power amplifier. In an embodiment, harmonic control circuit networks **3410**-{**1**, . . . , n} are selected such that energy transfer to the fundamental harmonic in the summed output spectrum is increased while the harmonic content of the output waveform is decreased. A further description of harmonic control according to embodiments of the present invention is provided below in section 3.6.

[0485] FIG. **35** is a block diagram that illustrates another power amplifier (PA) output stage embodiment **3500** according to the present invention. Output stage embodiment **3500** represents a differential output equivalent of output stage embodiment **3200** of FIG. **32**. In embodiment **3500**, PA stage outputs **3510**-{**1**, . . . , n} are combined successively to result in two aggregate signals. The two aggregate signals are then combined across a loading impedance, thereby having the output of the power amplifier represent the difference between the two aggregate signals. Referring to FIG. **35**, aggregate signals **3510** and **3520** are coupled across loading impedance **3530**. The output of the power amplifier is measured across the loading impedance **3530** as the voltage difference between nodes **3540** and **3550**. According to embodiment **3500**, the maximum output of the power amplifier is obtained when the two aggregate signals are 180 degrees out-of-phase relative to each other. Inversely, the minimum output power results when the two aggregate signals are in-phase relative to each other.

[0486] FIG. **36** is a block diagram that illustrates another output stage embodiment **3600** according to the present invention. Similar to the embodiment of FIG. **30**, output stage **3600** includes a plurality of PA branches **3605**-{**1**, . . . , n}. Each of PA branches {**1**, . . . , n} may include multiple power amplification stages represented by a pre-driver **3020**-{**1**, . . . , n}, a driver **3030**-{**1**, . . . , n}, and a power amplifier (PA) **3620**-{**1**, . . . , n}.

[0487] According to embodiment **3600**, PA's **3620**-{**1**, . . . , n} include switching power amplifiers. In the example of FIG. **36**, power amplifiers **3620**-{**1**, . . . , n} include npn bipolar junction transistor (BJT) elements Q**1**, . . . , Qn. BJT elements Q**1**, . . . , Qn have common collector nodes. Referring to FIG. **36**, collector terminals of BJT elements Q**1**, . . . , Qn are coupled together to provide summing node **3640**. Emitter terminals of BJT elements Q**1**, . . . , Qn are coupled to a ground node, while base terminals of BJT elements Q**1**, . . . , Qn provide input terminals into the PA stage.

[0488] FIG. **37** is an example (related to FIG. **36**) that illustrates an output signal of the PA stage of embodiment **3600** in response to square wave input signals. For ease of illustration, a two-branch PA stage is considered. In the example of FIG. **37**, square wave signals **3730** and **3740** are input, respectively, into BJT elements **3710** and **3720**. Note than when either of BJT elements **3710** or **3720** turns on, summing node **3750** is shorted to ground. Accordingly, when either of input signals **3730** or **3740** is high, output signal **3780** will be zero. Further, output signal **3780** will be high only when both input signals **3730** and **3740** are zero. According to this arrangement, PA stage **3700** performs pulse-width modulation, whereby the magnitude of the output signal is a function of the phase shift angle between the input signals.

[0489] Embodiments are not limited to npn BJT implementations as described herein. A person skilled in the art will appreciate, for example, that embodiments of the present invention may be implemented using pnp BJTs, CMOS, NMOS, PMOS, or other type of transistors. Further, embodiments can be implemented using GaAs and/or SiGe transistors with the desired transistor switching speed being a factor to consider.

[0490] Referring back to FIG. **36**, it is noted that while PAs **3620**-{**1**, . . . , n) are each illustrated using a single BJT notation, each PA **3620**-{**1**, . . . , n} may include a plurality of series-coupled transistors. In embodiments, the number of transistors included within each PA is set according to a required maximum output power level of the power amplifier. In other embodiments, the number of transistors in the PA is such that the numbers of transistors in the pre-driver, driver, and PA stages conform to a geometric progression.

[0491] FIG. **38** illustrates an exemplary PA embodiment **3800** according to an embodiment of the present invention. PA embodiment **3800** includes a BJT element **3870**, a LC network **3860**, and a bias impedance **3850**. BJT element **3870** includes a plurality of BJT transistors Q**1**, . . . , Q**8** coupled in series. As illustrated in FIG. **38**, BJT transistors Q**1**, . . . , Q**8** are coupled together at their base, collector, and emitter terminals. Collector terminal **3880** of BJT element **3870** provides an output terminal for PA **3800**. Emitter terminal **3890** of BJT element **3870** may be coupled to substrate or to an emitter terminal of a preceding amplifier stage. For example, emitter terminal **3890** is coupled to an emitter terminal of a preceding driver stage.

[0492] Referring to FIG. **38**, LC network **3860** is coupled between PA input terminal **3810** and input terminal **3820** of BJT element **3870**. LC network **3860** includes a plurality of capacitive and inductive elements. Optionally, a Harmonic Control Circuit network **3830** is also coupled at input terminal **3820** of BJT element **3870**. As described above, the HCC network **3830** provides a harmonic control function for controlling the output frequency spectrum of the power amplifier.

[0493] Still referring to FIG. **38**, bias impedance **3850** couples Iref signal **3840** to input terminal **3820** of BJT element **3870**. Iref signal **3840** represents an autobias signal that controls the bias of BJT element **3870** according to a desired output power level and signal envelope characteristics.

[0494] It is noted that, in the embodiment of FIG. **38**, BJT element **3870** is illustrated to include 8 transistors. It can be appreciated by a person skilled in the art, however, that BJT element **3870** may include any number of transistors as required to achieve the desired output power level of the power amplifier.

[0495] In another aspect, output stage embodiments can be implemented using multiple-input single-output (MISO) power amplifiers. FIG. **51**A is a block diagram that illustrates an exemplary MISO output stage embodiment **5100**A. Output stage embodiment **5100**A includes a plurality of vector modulator signals **5110**-{**1**, . . . , n} that are input into MISO power amplifier (PA) **5120**. As described above, signals **5110**-{**1**, . . . , n} represent constant envelope constituents of output signal **5130** of the power amplifier. MISO PA **5120** is a multiple input single output power amplifier. MISO PA **5120** receives and amplifies signals **5110**-{**1**, . . . , n} providing a distributed multi signal amplification process to generate output signal **5130**.

[0496] It is noted that MISO implementations, similar to the one shown in FIG. **51**A, can be similarly extended to any of the output stage embodiments described above. More specifically, any of the output stage embodiments of FIGS. **29**-**37** can be implemented using a MISO approach. Additional MISO embodiments will now be provided with reference to FIGS. **51**B-I. It is noted that any of the embodiments described above can be implemented using any of the MISO embodiments that will now be provided.

[0497] Referring to FIG. **51**A, MISO PA **5120** can have any number of inputs as required by the substantially constant envelope decomposition of the complex envelope input signal. For example, in a two-dimensional decomposition, a two-input power amplifier can be used. According to embodiments of the present invention, building blocks for creating MISO PAs for any number of inputs are provided. FIG. **51**B illustrates several MISO building blocks according to an embodiment of the present invention. MISO PA **5110**B represents a two-input single-output PA block. In an embodiment, MISO PA **5110**B includes two PA branches. The PA branches of MISO PA **5110**B may be equivalent to any PA branches described above with reference to FIGS. **29**-**37**, for example. MISO PA **5120**B represents a three-input single-output PA block. In an embodiment, MISO PA **5120**B includes three PA branches. The PA branches of MISO PA **5120**B may equivalent to any PA branches described above with reference to FIGS. **29**-**37**, for example.

[0498] Still referring to FIG. **51**B, MISO PAs **5110**B and **5120**B represent basic building blocks for any multiple-input single-output power amplifier according to embodiments of the present invention. For example, MISO PA **5130**B is a four-input single-output PA, which can be created by coupling together the outputs of two two-input single-output PA blocks, such as MISO PA **5110**B, for example. This is illustrated in FIG. **51**C. Similarly, it can be verified that MISO PA **5140**B, an n-input single-output PA, can be created from the basic building blocks **5110**B and **5120**B.

[0499] FIG. **51**D illustrates various embodiments of the two-input single output PA building block according to embodiments of the present invention.

[0500] Embodiment **5110**D represents an npn implementation of the two-input single output PA building block. Embodiment **5110**D includes two npn transistors coupled together using a common collector node, which provides the output of the PA. A pull-up impedance (not shown) can be coupled between the common collector node and a supply node (not shown).

[0501] Embodiment **5130**D represents a pnp equivalent of embodiment **5110**. Embodiment **5130**D includes two pnp transistors coupled at a common collector node, which provides the output of the PA. A pull-down impedance (not shown) can be coupled between the common collector node and a ground node (not shown).

[0502] Embodiment **5140**D represents a complementary npn/pnp implementation of the two-input single output PA building block. Embodiment **5140**D includes an npn transistor and a pnp transistor coupled at a common collector node, which provides the output of the PA.

[0503] Still referring to FIG. **51**D, embodiment **5120**D represents a NMOS implementation of the two-input single output PA building block. Embodiment **5120**D includes two NMOS transistors coupled at a common drain node, which provides the output of the PA.

[0504] Embodiment **5160**D represents an PMOS equivalent of embodiment **5120**D. Embodiment **5120**D includes two PMOS transistors coupled at a common drain node, which provides the output of the PA.

[0505] Embodiment **5150**D represents a complementary MOS implementation of the two-input single-output PA building block. Embodiment **5150**D includes a PMOS transistor and an NMOS transistor coupled at common drain node, which provides the output of the PA.

[0506] Two-input single-output embodiments of FIG. **51**D can be further extended to create multiple-input single-output PA embodiments. FIG. **51**E illustrates various embodiments of multiple-input single-output PAs according to embodiments of the present invention.

[0507] Embodiment **5150**E represents an npn implementation of a multiple-input single-output PA. Embodiment **5150**E includes a plurality of npn transistors coupled together using a common collector node, which provides the output of the PA. A pull-up impedance (not shown) can be coupled between the common collector node and a supply voltage (not shown). Note that an n-input single-output PA according to embodiment **5150**E can be obtained by coupling additional npn transistors to the two-input single-output PA building block embodiment **5110**D.

[0508] Embodiment **5170**E represents a pnp equivalent of embodiment **5150**E. Embodiment **5170**E includes a plurality of pnp transistors coupled together using a common collector node, which provides the output of the PA. A pull-down impedance (not shown) may be coupled between the common collector node and a ground node (not shown). Note than an n-input single-output PA according to embodiment **5170**E can be obtained by coupling additional pnp transistors to the two-input single-output PA building block embodiment **5130**D.

[0509] Embodiments **5110**E and **5130**E represent complementary npn/pnp implementations of a multiple-input single-output PA. Embodiments **5110**E and **5130**E may include a plurality of npn and/or pnp transistors coupled together using a common collector node, which provides the output of the PA. Note that an n-input single-output PA according to embodiment **5110**E can be obtained by coupling additional npn and/or pnp transistors to the two-input single-output PA building block embodiment **5140**D. Similarly, an n-input single-output PA according to embodiment **5130**E can be obtained by coupling additional npn and/or pnp transistors to the two-input single-output PA building block embodiment **5130**D.

[0510] Embodiment **5180**E represents an PMOS implementation of a multiple-input single-output PA. Embodiment **5180**E includes a plurality of PMOS transistors coupled together using a common drain node, which provides the output of the PA. Note that an n-input single-output PA according to embodiment **5180**E can be obtained by coupling additional NMOS transistors to the two-input single-output PA building block embodiment **5160**D.

[0511] Embodiment **5160**E represents a NMOS implementation of multiple-input single-output PA. Embodiment **5160**E includes a plurality of NMOS transistors coupled together using a common drain node, which provides the output of the PA. Note that an n-input single-output PA according to embodiment **5160**E can be obtained by coupling additional PMOS transistors to the two-input single-output PA building block embodiment **5120**D.

[0512] Embodiments **5120**E and **5140**E complementary MOS implementations of a multiple-input single-output PA. Embodiments **5120**E and **5140**E include a plurality of npn and pnp transistors coupled together using a common drain node, which provides the output of the PA. Note that a n-input single-output PA according to embodiment **5120**E can be obtained by coupling additional NMOS and/or PMOS transistors to the two-input single-output PA building block **5150**D. Similarly, an n-input single-output PA according to embodiment **5140**E can be obtained by coupling additional NMOS and/or PMOS transistors to the two-input single-output PA building block **5160**D.

[0513] FIG. **51**F illustrates further multiple-input single-output PA embodiments according to embodiments of the present invention. Embodiment **5110**F represents a complementary npn/pnp implementation of a multiple-input single-output PA. Embodiment **5110**F can be obtained by iteratively coupling together embodiments of PA building block **5140**D. Similarly, embodiment **5120**F represents an equivalent NMOS/PMOS complementary implementation of a multiple-input single-output PA. Embodiment **5120**F can be obtained by iteratively coupling together embodiments of PA building block **5150**D.

[0514] It must be noted that the multiple-input single-output embodiments described above may each correspond to a single or multiple branches of a PA. For example, referring to FIG. **29**, any of the multiple-input single-output embodiments may be used to replace a single or multiple PAs **2920**-{**1**, . . . , n}. In other words, each of PAs **2920**-{**1**, . . . , n} may be implemented using any of the multiple-input single-output PA embodiments described above or with a single-input single-output PA as shown in FIG. **29**.

[0515] It is further noted that the transistors shown in the embodiments of FIGS. **51**D, **51**E, and **51**F may each be implemented using a series of transistors as shown in the exemplary embodiment of FIG. **38**, for example.

[0516] FIG. **51**G illustrates further embodiments of the multiple-input single-output PA building blocks. Embodiment **5110**G illustrates an embodiment of the two-input single-output PA building block. Embodiment **5110**G includes two PA branches that can each be implemented according to single-input single-output or multiple-input single-output PA embodiments as described above. Further, embodiment **5110**G illustrates an optional bias control signal **5112**G that is coupled to the two branches of the PA embodiment. Bias control signal **5112**G is optionally employed in embodiment **5110**G based on the specific implementation of the PA branches. In certain implementations, bias control will be required for proper operation of the PA. In other implementations, bias control is not required for proper operation of the PA, but may provide improved PA power efficiency, output circuit protection, or power on current protection.

[0517] Still referring to FIG. **51**G, embodiment **5120**G illustrates an embodiment of the three-input single-output PA building block. Embodiment **5120**G includes three PA branches that can each be implemented according to single-input single-output or multiple-input single-output PA embodiments as described above. Further, embodiment **5120**G illustrates an optional bias control signal **5114**G that is coupled to the branches of the PA embodiment. Bias control signal **5114**G is optionally employed in embodiment **5120**G based on the specific implementation of the PA branches. In certain implementations, bias control will be required for proper operation of the PA. In other implementations, bias control is not required for proper operation of the PA, but may provide improved PA power efficiency.

[0518] FIG. **51**H illustrates a further exemplary embodiment **5100**H of the two-input single-output. PA building block. Embodiment **5100**H includes two PA branches that can each be implemented according to single-input single-output or multiple-input single-output PA embodiments as described above. Embodiment **5100**H further includes optional elements, illustrated using dashed lines in FIG. **51**H, that can be additionally employed in embodiments of embodiment **5100**H. In an embodiment, PA building block **5100**H may include a driver stage and/or pre-driver stage in each of the PA branches as shown in FIG. **51**H. Process detectors may also be optionally employed to detect process and temperature variations in the driver and/or pre-driver stages of the PA. Further, optional bias control may be provided to each of the pre-driver, driver, and/or PA stages of each branch of the PA embodiment. Bias control may be provided to one or more the stages based on the specific implementation of that stage. Further, bias control may be required for certain implementations, while it can be optionally employed in others.

[0519] FIG. **51**I illustrates a further exemplary embodiment **5100**I of a multiple-input single-output PA. Embodiment **5100**I includes at least two PA branches that can each be implemented according to single-input single-output or multiple-input single-output PA embodiments as described above. Embodiment **5100**I further includes optional elements that can be additionally employed in embodiments of embodiment **5100**I. In an embodiment, the PA may include driver and/or pre-driver stages in each of the PA branches as shown in FIG. **51**I. Process detectors may also be optionally employed to detect process and temperature variations in the driver and/or pre-driver stages of the PA. Further, optional bias control may be provided to each of the pre-driver, driver, and/or PA stages of each branch of the PA embodiment. Bias control may be provided to one or more the stages based on the specific implementation of that stage.

Further, bias control may be required for certain implementations, while it can be optionally employed in others.

3.5.2) Output Stage Current Control —Autobias Module

[0520] Embodiments of the output stage and optional pre-driver and driver stage bias and current control techniques according to embodiments of the present invention are described below. In certain embodiments, output stage current control functions are employed to increase the output stage efficiency of a vector power amplifier (VPA) embodiment In other embodiments, output stage current control is used to provide output stage protection from excessive voltages and currents which is further describe in section 3.5.3. In embodiments, output stage current control functions are performed using the Autobias module described above with reference to FIG. **33**. A description of the operation of the Autobias module in performing these current control functions is also presented below according to an embodiment of the present invention.

[0521] According to embodiments of the present invention, power efficiency of the output stage of a VPA can be increased by controlling the output stage current of the VPA as a function of the output power and the envelope of the output waveform.

[0522] FIG. **37**, illustrates a partial schematic of a Multiple Input Single Output amplifier comprised of two NPN transistors with input signals S1 and S2. When S1 and S2 are designed to be substantially similar waveforms and substantially constant envelope signals, any time varying complex-envelope output signal can be created at circuit node **3750** by changing the phase relationship of S1 and S2.

[0523] FIG. **39** illustrates an example time varying complex-envelope output signal **3910** and its corresponding envelope signal **3920**. Note than signal **3910** undergoes a reversal of phase at an instant of time t_0. Correspondingly, envelope signal **3920** undergoes a zero crossing at time to. Output signal **3910** exemplifies output signals according to typical wireless signaling schemes such as W-CDMA, QPSK, and OFDM, for example.

[0524] FIG. **40** illustrates example diagram FIG. **37**'s output stage current in response to output signal **3910**. I_{out} signal **4010** represents output stage current without autobias control, and I_{out} signal **4020** represents output stage current with autobias control. Without autobias control, as the phase shift between S1 and S2 changes from 0 to 180 degrees, the output current I_{out} increases. With autobias control, the output current I_{out} decreases and can be minimized when at or near t_0 of FIG. **39**.

[0525] Note that I_{out} signal **4020** varies as a function of envelope signal **3920**. Accordingly, I_{out} signal **4020** is at the maximum when a maximum output power is required, but decreases as the required output power goes down. Particularly, I_{out} signal **4020** approaches zero as the associated output power goes to zero. Accordingly, a person skilled in the art will appreciate that output stage current control, according to embodiments of the present invention, results in significant power savings and increases the power efficiency of the power amplifier.

[0526] According to embodiments of the present invention, output stage current control may be implemented according to a variety of functions. In an embodiment, the output stage current can be shaped to correspond to the desired output power of the amplifier. In such an embodiment, the output stage current is a function that is derived from the envelope of the desired output signal, and the power efficiency will increase.

[0527] FIG. **41** illustrates exemplary autobias output stage current control functions **4110** and **4120** according to embodiments of the present invention. Function **4110** may represent a function of output power and signal envelope as described above. On the other hand, function **4120** may represent a simple shaping function that goes to a minimum value for a pre-determined amount of time when the output power is below a threshold value. Accordingly, functions **4110** and **4120** represent two cases of autobias output stage current control functions with autobias control signal **4110** resulting in I_{out} response **4130** and autobias control signal **4120** resulting in I_{out} response **4140**. The invention, however, is not limited to those two exemplary embodiments. According to embodiments of the present invention, output stage autobias current control functions may be designed and implemented to accommodate the efficiency and current consumption requirements of a particular vector power amplifier design.

[0528] In implementation, several approaches exist for performing output stage current control. In some embodiments, output stage current shaping is performed using the Autobias module. The Autobias module is illustrated as autobias circuitry **714** and **716** in the embodiments of FIGS. **7** and **8**. Similarly, the Autobias module is illustrated as autobias circuitry **1218** in the embodiments of FIGS. **12** and **13**, and as autobias circuitry **1718** in the embodiments of FIGS. **17** and **18**.

[0529] Output stage current control using Autobias is depicted in process flowchart **4800** of the embodiment of FIG. **48**. The process begins in step **4810**, which includes receiving output power and output signal envelope information of a desired output signal of a vector power amplifier (VPA). In some embodiments, implementing output stage current control using Autobias requires a priori knowledge of the desired output power of the amplifier. Output power information may be in the form of envelope and phase information. For example, in the embodiments of FIGS. **7**, **8**, **12**, **13**, **17**, and **18**, output power information is included in I and Q data components received by the VPA embodiment. In other embodiments, output power information may be received or calculated using other means.

[0530] Step **4820** includes calculating a signal according to the output power and output envelope signal information. In embodiments, an Autobias signal is calculated as a function of some measure of the desired output power. For example, the Autobias signal may be calculated as a function of the envelope magnitude of the desired output signal. Referring to the embodiments of FIGS. **7**, **8**, **12**, **13**, **17**, and **18**, for example, it is noted that the Autobias signal (signals **715** and **717** in FIGS. **7** and **8**, signal **1228** in FIGS. **12** and **13**, and signals **1728** in FIGS. **17** and **18**) is calculated according to received I and Q data components of a desired output signal. In certain embodiments, such as the ones described in FIGS. **7**, **8**, **12**, **13**, **17**, and **18**, the Autobias signal is calculated by an Autobias module being provided output power information. In other embodiments, the Autobias signal may be calculated by the I and Q Data Transfer Function module(s) of the VPA. In such embodiments, an Autobias module may not be required in implementation. In embodiments, the I and Q Data Transfer Function module calculates a signal, outputs the signal to a DAC which output signal represents the Autobias signal.

[0531] Step **4830** includes applying the calculated signal at an output stage of the VPA, thereby controlling a current of the output stage according to the output power of the desired output signal. In embodiments, step **4830** includes coupling the Autobias signal at the PA stage input of the VPA. This is illustrated, for example, in the embodiments of FIGS. **33** and **42** where Autobias signal **3310** is coupled at the PA stage input of the VPA embodiment. In these embodiments, Autobias signal **3310** controls the bias of the PA stage transistors according to the output power of the desired output signal of the VPA embodiment. For example, Autobias signal **3310** may cause the PA stage transistors to operate in cutoff state when the desired output power is minimal or near zero, thereby drawing little or no output stage current. Similarly, when a maximum output power is desired, Autobias signal **3310** may bias the PA stage transistors to operate in class C,D,E, etc. switching mode. Autobias signal **3310** may also cause the PA stage transistors or FETs to operate in forward or reverse biased states according to the desired output power and signal envelope characteristics.

[0532] In other embodiments, step **4830** includes coupling the Autobias signal using pull-up impedances at the PA stage input and optionally the inputs of the driver and pre-driver stages of the VPA. FIGS. **38** and **43** illustrate such embodiments. For example, in the embodiment of FIG. **38**, bias impedance **3850** couples Autobias Iref signal **3840** to input terminal **3820** of BJT element **3870**. BJT element **3870** represents the PA stage of one PA branch of an exemplary VPA embodiment. Similarly, in the embodiment of FIG. **43**, Autobias signal **4310** is coupled to transistors **Q1**, . . . , **Q8** through corresponding bias impedances **Z1**, . . . , **Z8**. Transistors **Q1**, . . . , **Q8** represent the PA stage of one branch of an exemplary VPA embodiment.

[0533] Embodiments for implementing the Autobias circuitry described above will now be provided. FIG. **27** illustrates three embodiments **2700**A, **2700**B, and **2700**C for implementing the Autobias circuitry. These embodiments are provided for illustrative purposes, and are not limiting. Other embodiments will be apparent to persons skilled in the art(s) based on the teachings contained herein.

[0534] In embodiment **2700**A, Autobias circuitry **2700**A includes an Autobias Transfer Function module **2712**, a DAC **2714**, and an optional interpolation filter **2718**. Autobias circuitry **2700**A receives an I and Q Data signal **2710**. Autobias Transfer Function module **2712** processes the received I and Q Data signal **2710** to generate an appropriate bias signal **2713**. Autobias Transfer Function module **2712** outputs bias signal **2713** to DAC **2714**. DAC **2714** is controlled by a DAC clock **2716** which may be generated in Autobias transfer module **2712**. DAC **2714** converts bias signal **2713** into an analog signal, and outputs the analog signal to interpolation filter **2718**. Interpolation filter **2718**, which also serves as an anti-aliasing filter, shapes the DAC's output to generate Autobias signal **2720**, illustrated as Bias A in embodiment **5112**G. Autobias signal **2720** may be used to bias the PA stage and/or the driver stage, and/or the pre-driver stage of the amplifier. In an embodiment, Autobias signal **2720** may have several other Autobias signals derived therefrom to bias different stages within the PA stage. This can be done using additional circuitry not included in embodiment **2700**A.

[0535] In contrast, embodiment **2700**B illustrates an Autobias circuitry embodiment in which multiple Autobias signals are derived within the Autobias circuitry. As shown in embodiment **2700**B, circuit networks **2722**, **2726**, and **2730**, illustrated as circuit networks A, B, and C in embodiment **2700**B, are used to derive Autobias signals **2724** and **2728** from Autobias signal **2720**. Autobias signals **2720**, **2724**, and **2728** are used to bias different amplification stages.

[0536] Embodiment **2700**C illustrates another Autobias circuitry embodiment in which multiple Autobias signals are generated independently within the Autobias Transfer Function module **2712**. In embodiment **2700**C, Autobias Transfer Function module **2712** generates multiple bias signals according to the received I and Q Data signal **2710**. The bias signals may or may not be related. Autobias Transfer Function module **2712** outputs the generated bias signals to subsequent DACs **2732**, **2734**, and **2736**. DACs **2732**, **2734**, and **2736** are controlled by DAC clock signals **2733**, **2735**, and **2737**, respectively. DACs **2732**, **2734**, and **2736** convert the received bias signals into analog signals, and output the analog signals to optional interpolation filters **2742**, **2744**, and **2746**. Interpolation filters **2742**, **2744**, and **2746**, which also serve as anti-aliasing filters, shape the DACs outputs to generate Autobias signals **2720**, **2724**, and **2728**. Similar to embodiment **2700**B, Autobias signals **2720**, **2724**, and **2728** are used to bias different amplification stages such as the pre-driver, driver, and PA.

[0537] As noted above, Autobias circuitry embodiments according to the present invention are not limited to the ones described in embodiments **2700**A, **2700**B, and **2700**C. A person skilled in the art will appreciate, for example, that Autobias circuitry can be extended to generate any number of bias control signals as required to control the bias of various stages of amplification, and not just three as shown in embodiments **5200**B and **5200**C, for example.

3.5.3) Output Stage Protection

[0538] As described above, output stage embodiments according to embodiments of the present invention are highly power efficient as a result of being able to directly couple outputs at the PA stage using no combining or isolating elements. Certain output stage embodiments in certain circumstances and/or applications, however, may require additional special output stage protection measures in order to withstand such direct coupling approach. This may be the case for example for output stage embodiments such as **5110**D, **5120**D, **5130**D, **5160**D, **5150**E, **5160**E, **5170**E, and **5180**E illustrated in FIGS. **51**D and **51**E. Note that, generally, complementary output stage embodiments, such as embodiments **5140**D, **5150**D, **5110**E, **5120**E, **5130**E, and **5140**E of FIGS. **51**D and **51**E, do not require (but may optionally use) the same output stage protection measures as will be described herein in this section. Output stage protection measures and embodiments to support such measures are now provided.

[0539] In one aspect, transistors of distinct branches of a PA stage should generally not simultaneously be in opposite states of operation for extended periods of time. Following a restart or power on with no inputs being supplied to the final PA stages, transients within the PA branches may cause this mode to occur resulting in the PA stage transistors potentially damaging one another or circuit elements connected to the output. Accordingly, embodiments of the present invention further constrain the Autobias module to limit the output current in the PA stage.

[0540] In another aspect, it may be desired to ensure that the Autobias module limits the output voltages below the breakdown voltage specification of the PA stage transistors. Accordingly, in embodiments of the present invention, such as the one illustrated in FIG. **42** for example, a feedback element **4210** is coupled between the common collector node of the PA stage and the Autobias module. Feedback element **4210** monitors the collector to base voltage of the PA stage transistors, and may constrain the Autobias signal as necessary to protect the transistors and/or circuit elements.

[0541] A person skilled in the art will appreciate that other output stage protection techniques may also be implemented. Furthermore, output stage protection techniques may be implementation specific. For example, depending on the type of PA stage transistors (npn, pnp, NMOS, PMOS, npn/pnp, NMOS/PMOS), different protection functions may be required.

3.6) Harmonic Control

[0542] According to embodiments of the present invention, an underlying principle for each branch PA is to maximize the transfer of power to a fundamental harmonic of the output spectrum. Typically, each branch PA may be multi-stage giving rise to a harmonically rich output spectrum. In one aspect, transfer of real power is maximized for the fundamental harmonic. In another aspect, for non-fundamental harmonics, real power transfer is minimized while imaginary power transfer may be tolerated. Harmonic control, according to embodiments of the present invention, may be performed in a variety of ways.

[0543] In one embodiment, real power transfer onto the fundamental harmonic is maximized by means of waveshaping of the PA stage input signals. In practice, several factors play a role in determining the optimal wave shape that results in a maximum real power transfer onto the fundamental harmonic. Embodiment **3400** of the present invention, described above, represents one embodiment that employs waveshaping of PA stage input signals. In embodiment **3400**, a plurality of harmonic control circuitry (HCC) networks **3410**-{**1**, . . . , n} are coupled at the PA stage input of each PA branch {**1**, . . . , n}. HCC networks **3410**-{**1**, . . . , n} have the effect of waveshaping the PA stage inputs, and are typically selected so as to maximize real power transfer to the fundamental harmonic of the summed output spectrum. According to embodiments of the present invention, waveshaping can be used to generate variations of harmonically diverse waveforms. In other embodiments, as can be apparent to a person skilled in the art, waveshaping can be performed at the pre-driver and/or the driver stage.

[0544] In another embodiment, harmonic control is achieved by means of waveshaping of the PA stage output. FIG. **43** illustrates an exemplary PA stage embodiment **4300** of the present invention. In embodiment **4300**, Autobias signal **4310** is coupled to transistors Q**1**, . . . , Q**8** through corresponding bias impedances Z**1**, . . . , Z**8**. Notice that when impedances Z**1**, . . . , Z**8** have different values, transistors Q**1**, . . . , Q**8** have different bias points and can be turned on at different times. This approach of biasing transistors Q**1**, . . . , Q**8** is referred to as staggered bias. Note that using staggered bias, the PA output waveform can be shaped in a variety of ways depending on the values assigned to bias impedances Z**1**, . . . , Z**8**.

[0545] Harmonic control using staggered bias is depicted in process flowchart **4900** of the embodiment of FIG. **49**. The process begins in step **4910**, which includes coupling an input signal at first ports of a plurality of transistors of a power amplifier (PA) switching stage. In the example embodiment of FIG. **43**, for example, step **4910** corresponds to coupling PA_IN signal **4310** at base terminals of the plurality of transistors Q**1**, . . . , Q**8**.

[0546] Step **4920** includes coupling a plurality of impedances between the first ports of the plurality of transistors and a bias signal. In the example embodiment of FIG. **43**, for example, step **4920** is achieved by coupling impedances Z**1**, . . . , Z**8** between base terminals of respective transistors Q**1**, . . . , Q**8** and Iref signal. In an embodiment, values of the plurality of impedances are selected to cause a time-staggered switching of the input signal, thereby harmonically shaping an output signal of the PA stage. In embodiments, a multi-stage staggered output may be generated by selecting multiple distinct values of the plurality of impedances. In other embodiments, switching is achieved by selecting the plurality of impedances to have equal or substantially equal value.

[0547] FIG. **44** illustrates an exemplary wave-shaped PA output using a two-stage staggered bias approach. In a two-stage staggered bias approach, a first set of the PA transistors is first turned on before a second set is turned on. In other words, the bias impedances take two different values. Waveform **4410** represents an input waveform into the PA stage. Waveform **4420** represents the wave-shaped PA output according to a two-stage staggered bias. Notice that output waveform **4420** slopes twice as it transitions from 1 to 0, which corresponds to the first and second sets of transistors turning on successively.

[0548] According to embodiments of the present invention, a variety of multi-stage staggered bias approaches may be designed. Bias impedance values may be fixed or variable. Furthermore, bias impedance values may be equal or substantially equal, distinct, or set according to a variety of permutations. For example, referring to the example of FIG. **43**, one exemplary permutation might set Z**1**=Z**2**=Z**3**=Z**4** and Z**5**=Z**6**=Z**7**=Z**8** resulting in a two-stage staggered bias.

3.7) Power Control

[0549] Vector power amplification embodiments of the present invention intrinsically provide a mechanism for performing output power control.

[0550] FIG. **45** illustrates one approach for performing power control according to an embodiment of the present invention. In FIG. **45**, phasors $\vec{U}_1$ and $\vec{L}_1$ represent upper and lower constituents of a first phasor $\vec{R}_1$. $\vec{U}_1$ and $\vec{L}_1$**0** are constant magnitude and are symmetrically shifted in phase relative to $\vec{R}_1$ by a phase shift angle

$$\frac{\phi}{2}.$$

Phasors $\vec{U}_2$ and $\vec{L}_2$ represent upper and lower constituents of a second phasor $\vec{R}_2$. $\vec{U}_2$ and $\vec{L}_2$ are constant magnitude and are symmetrically shifted in phase relative to $\vec{R}_2$ by a phase shift angle

$$\frac{\phi}{2}+\phi_{off}.$$

[0551] It is noted, from FIG. **45**, that $\vec{R}_1$ and $\vec{R}_2$ are in-phase relative to each other but only differ in magnitude. Furthermore, $\vec{U}_2$ and $\vec{L}_2$ are equally or substantially equally phased shifted relative to $\vec{U}_1$ and $\vec{L}_1$, respectively. Accordingly, it can be inferred that, according to the present invention, a signal's magnitude can be manipulated without varying its phase shift angle by equally or substantially equally shifting symmetrically its constituent signals.

[0552] According to the above observation, output power control can be performed by imposing constraints on the phase shift angle of the constituent signals of a desired output signal. Referring to FIG. **45**, for example, by constraining the range of values that phase shift angle

$$\frac{\phi}{2}$$

can take, magnitude constraints can be imposed on phasor $\vec{R}_1$.

[0553] According to embodiments of the present invention, a maximum output power level can be achieved by imposing a minimum phase shift angle condition. For example, referring to FIG. **45**, by setting a condition such that

$$\frac{\phi}{2}\geq\phi_{ff},$$

the magnitude of phasor $\vec{R}_1$ is constrained not to exceed a certain maximum level. Similarly, a maximum phase shift angle condition imposes a minimum magnitude level requirement.

[0554] In another aspect of power control, output power resolution is defined in terms of a minimum power increment or decrement step size. According to an embodiment of the present invention, output power resolution may be implemented by defining a minimum phase shift angle step size. Accordingly, phase shift angle values are set according to a discrete value range having a pre-determined step size. FIG. **46** illustrates an exemplary phase shift angle spectrum, whereby phase shift angle

$$\frac{\phi}{2}$$

is set according to a pre-determined value range having a minimum step ϕ_{step}.

[0555] A person skilled in the art will appreciate that a variety of power control schemes may be implemented in a fashion similar to the techniques described above. In other words, various power control algorithms can be designed, according to the present invention, by setting corresponding constraints on phase shift angle values. It is also apparent, based on the description above of data transfer functions, that power control schemes can be naturally incorporated into a transfer function implementation.

3.8) Exemplary Vector Power Amplifier Embodiment

[0556] FIG. **47** illustrates an exemplary embodiment **4700** of a vector power amplifier according to the present invention. Embodiment **4700** is implemented according to the Direct Cartesian 2-Branch VPA method.

[0557] Referring to FIG. **47**, signals **4710** and **4712** represent incoming signals from a transfer function stage. The transfer function stage is not shown in FIG. **47**. Block **4720** represents a quadrature generator which may be optionally implemented according to an embodiment of the present invention. Quadrature generator **4720** generates clock signals **4730** and **4732** to be used by vector modulators **4740** and **4742**, respectively. Similarly, signals **4710** and **4712** are input into vector modulators **4740** and **4742**. As described above, vector modulators **4740** and **4742** generate constant envelope constituents that are, subsequently, processed by a PA stage. In embodiment **4700**, the PA stage is multi-stage, whereby each PA branch includes a pre-driver stage **4750-4752**, a driver stage **4760-4762**, and a power amplifier stage **4770-4772**.

[0558] Further illustrated in FIG. **47** are Autobias signals **4774** and **4776**, and terminals **4780** and **4782** for coupling harmonic control circuitry and networks. Terminal node **4780** represents the output terminal of the vector power amplifier, and is obtained by direct coupling of the two PA branches' outputs.

4. Additional Exemplary Embodiments and Implementations

4.1) Overview

[0559] Exemplary VPA implementations according to embodiments of the present invention will be provided in this section. Advantages of these VPA implementations will be appreciated by persons skilled in the art based on the teachings herein. We briefly describe below some of these advantages before presenting in more detail the exemplary VPA implementations.

4.1.1) Control of Output Power and Power Efficiency

[0560] The exemplary VPA implementations enable several layers of functionality for performing power control and/or for controlling power efficiency using circuitry within the VPA. FIG. **52** illustrates this functionality at a high level using a MISO VPA embodiment **5200**. MISO VPA embodiment **5200** is a 2 input single output VPA with optional driver and pre-driver stages in each branch of the VPA. As in previously described embodiments, the input bias voltage or current to each amplification stage (e.g., pre-driver stage, driver stage, etc.) of the VPA is controlled using a bias signal (also referred to as Autobias in other embodiments). In embodiment **5200**, separate bias signals Bias C, Bias B, and Bias A are coupled to the pre-driver, driver, and PA stages, respectively, of the VPA. Additionally, VPA embodiment **5200** includes power supply signals (Pre-Driver VSUPPLY, Driver VSUPPLY, and Output Stage VSUPPLY) that are used to power respective stages of the VPA. In embodiments, these power supply signals are generated using voltage controlled power supplies and can be further used to bias their respective amplifications stages, thereby providing additional functionality for controlling the overall power efficiency of the VPA and for performing power control, as well as other functions of the VPA. For example, when controlled independently, the power supply signals and bias signals can be used to operate different amplification stages of the VPA at different power supply voltages and bias points, enabling a wide output power dynamic range for the VPA. In embodiments the voltage controlled power supplies can be implemented as continuously variable supplies such as voltage controlled switching supplies which provide variable voltage supplies to the appropriate amplification stage. In other embodiments the voltage controlled power supply can be implemented by using switches to provide different power supply voltages. For example, a VPA output stage and/or optional driver stages and/or optional pre-driver stages power supply could be switched between 3.3V, 1.8V, and 0V depending on the desired operating parameters.

4.1.2) Error Compensation and/or Correction

[0561] The exemplary VPA implementations provide different approaches for monitoring and/or compensating for errors in the VPA. These errors may be due, among other factors, to process and/or temperature variations in the VPA, phase and amplitude errors in the vector modulation circuitry, gain and phase imbalances in branches of the VPA, and distortion in the MISO amplifier (see, for example, Section 3.4.5 above). In previously described VPA embodiments, part of this functionality was embodied in the process detector circuitry (e.g., process detector **792** in FIG. **7**A, process detector **1282** in FIG. **12**, process detector **1772** in FIG. **17**). These approaches can be classified as feedforward, feedback, and hybrid feedforward/feedback techniques, and can be implemented in a variety of ways as will be further discussed in the following sections that describe the exemplary VPA implementations. A conceptual description of these error monitoring and compensation approaches will be now provided.

[0562] FIGS. **54**A and **54**B are block diagrams that illustrate at a high level feedforward techniques for compensating for errors in a VPA. Feedforward techniques rely on a priori knowledge of expected errors in the VPA in order to pre-compensate for these errors within the VPA. Thus, feedforward techniques include an error measurement phase (typically performed in a test and characterization process) and a pre-compensation phase using the error measurements.

[0563] FIG. **54**A illustrates a process **5400**A for generating an error table or function that describes expected errors in I data and Q data at the output of the VPA (error measurement phase). Such errors are typically due to imperfections in the VPA. Process **5400**A is typically performed in a testing lab prior to finalizing the VPA design, and includes measuring at the output of a receiver I and Q values that correspond to a range of I and Q values at the input of the VPA. Typically, the input I and Q values are selected to generate a representative range of the 360° degrees polar space (for example, the I and Q values may be selected at a uniform spacing of 30° degrees). Subsequently, error differences between the input I and Q values and the output I and Q values are calculated. For example, after measuring I and Q at the output of the receiver for a particular set of I and Q input values, a compare circuitry calculates as I_{error} and Q_{error} or the differences in I data and Q data between the input I and Q values and the receiver output I and Q values. I_{error} and Q_{error} represent the expected errors in I and Q at the output of the VPA for the particular set of I and Q input values.

[0564] In an embodiment, the receiver is integrated with the VPA, or is provided by an external calibration and/or testing device. Alternatively, the receiver is the receiver module in the device employing the VPA (e.g., the receiver in a cellular phone). In this alternative embodiment, the VPA error table and/or feedback information can be generated by this receiver module in the device.

[0565] The calculated I_{error} and Q_{error} values are used to generate an error table or function representative of expected I and Q errors for various I and Q input values. In embodiments, the calculated I_{error} and Q_{error} values are further interpolated to generate error values for an augmented range of I and Q input values, based on which the error table or function is generated.

[0566] FIG. **54**B illustrates feedforward error pre-compensation (pre-compensation phase) according to an embodiment of the present invention. As illustrated, I and Q input values are corrected for any expected I_{error} and Q_{error} values as determined by an error table or function, prior to amplification by the VPA. I and Q error pre-compensation may be performed at different stages and/or at different temperatures and/or at different operating parameters within the VPA. In the embodiment of FIG. **54**B, error correction occurs prior to the amplification stage of the VPA. For example, I and Q error correction may be performed by the transfer function module of the VPA, such as transfer function modules **1216** and **1726** of FIGS. **12** and **17**, for example. Several methods exist for implementing I and Q error correction in the transfer function module of the VPA including using look up tables and/or digital logic to implement an error function. Typically, feedforward techniques require data storage such as RAM or NVRAM, for example, to store data generated in the measurement phase.

[0567] In contrast to feedforward techniques, feedback techniques do not pre-compensate for errors but perform real-time measurements inside or at the output of the VPA to detect any errors or deviations due to process or temperature variations, for example. FIG. **55** is a block diagram that conceptually illustrates an exemplary Cartesian feedback error correction technique according to embodiments of the present invention. As will be further described below, FIG. **55** illustrates a receiver-based feedback technique, in which the output of the VPA is received by a receiver, before being fed back to the VPA. Other feedback techniques according to embodiments of the present invention will be further described below. Feedback techniques may require additional circuitry to perform these real-time measurements, which may be made at different stages within the VPA, but require minimal or no data storage. Several implementations exist for feedback error correction as will be further described in the description of the exemplary VPA implementations below.

[0568] Hybrid feedforward/feedback techniques include both feedforward and feedback error pre-compensation and/or correction components. For example, a hybrid feedforward/feedback technique may pre-compensate for errors but may also use low rate periodical feedback mechanisms to supplement feedforward pre-compensation.

4.1.3) Multi-Band Multi-Mode VPA Operation

[0569] The exemplary VPA implementations provide several VPA architectures for concurrently supporting multiple frequency bands (e.g., quad band) and/or multiple technology modes (e.g., tri mode) for data transmission. Advantages of these VPA architectures will be appreciated by a person skilled in the art based on the teachings to be provided herein. In embodiments, the VPA architectures allow for using a single PA branch for supporting both TDD (Time Division Duplex) and FDD (Frequency Division Duplex) based standards. In other embodiments, the VPA architectures allow for the elimination of costly and power inefficient components at the output stage (e.g., isolators), typically required for FDD based standards. For the purpose of illustration and not limitation, frequency band allocation on lower and upper spectrum bands for various communication standards is provided in FIG. **53**. Note that the DCS **1800** (Digital Cellular System **1800**) and the PCS **1900** (Personal Communications Service **1900**) bands can support different GSM-based implementations, also known as GSM-**1800** and GSM-**1900**. The 3G TDD bands are allocated for third generation time division duplex standards such as UMTS TDD (Universal Mobile Telephone System) and TD-SCDMA (Time Division-Synchronous Code Division Multiple Access), for example. The 3G FDD bands are allocated for third generation frequency division duplex standards such as WCDMA (Wideband CDMA), for example.

[0570] As will be appreciated by persons skilled in the art based on the teachings herein, advantages enabled by the exemplary VPA implementations exist in various aspects in addition to those described above. In the following, a more detailed description of the exemplary VPA implementations will be provided. This includes a description of different implementations of the digital control circuitry of the VPA followed by a description of different implementations of the analog core of the VPA. Embodiments of the present invention are not limited to the specific implementations described herein. As will be understood by persons skilled in the art based on the teachings herein, several other VPA implementations may be obtained by combining features provided in the exemplary VPA implementations. Accordingly, the exemplary VPA implementations described below do not represent an exhaustive listing of VPA implementations according to embodiments of the present invention, and other implementations based on teachings contained herein are also within the scope of the present invention. For example, certain digital control circuitry could be integrated or combined with a baseband processor. In addition, certain analog control circuitry such as quadrature generators and vector modulators can be implemented using digital control circuitry. In an embodiment, the VPA system can be implemented in its entirety using digital circuitry and can be integrated completely with a baseband processor.

4.2) Digital Control Module

[0571] The digital control module of the VPA includes digital circuitry that is used, among other functions, for signal generation, performance monitoring, and VPA operation control. In Section 3, the signal generation functions of the digital control module (i.e., generating constant envelope signals) were described in detail with reference to the transfer function module (state machine) of the digital control module, in embodiments **700**, **1200**, and **1700**, for example. The performance monitoring functions of the digital control module include functions for monitoring and correcting for errors in the operation of the VPA and/or functions for controlling the bias of different stages of the VPA. The VPA operation control functions of the digital control module include a variety of control functions related to the operation of the VPA (e.g., powering up or programming VPA modules). In certain embodiments, these control functions may be optional. In other embodiments, these control functions are accessible through the digital control module to external processors connected to the VPA. In other embodiments, these functions are integrated with baseband processors or other digital circuitry. Other functions are also performed by the digital control module in addition to those described above. Digital control module functions and implementations will now be provided in further detail.

[0572] FIG. **56** is a high level illustration of a digital control module embodiment **5600** according to an embodiment of the present invention. Digital control module embodiment **5600** includes an input interface **5602**, an output interface **5604**, a state machine **5606**, a RAM (Random Access Memory) **5608**, and a NVRAM (Non-Volatile RAM) **5610**. In embodiments, Ram **5608**, and/or NVRAM **5610** may be optional.

[0573] Input interface **5602** provides a plurality of buses and/or ports for inputting signals into digital control module **5600**. These buses and/or ports include, for example, buses and/or ports for inputting I and Q data signals, control signals provided by an external processor, and/or clock signals. In an embodiment, input interface **5602** includes an I/O bus. In another embodiment, input interface **5602** includes a data bus for receiving feedback signals from the analog core of the VPA. In another embodiment, input interface **5602** includes ports for reading values out of digital control module **5600**. In an embodiment, values are read out of digital control module **5600** by an external processor (e.g., a baseband processor) connected to digital control module **5600**.

[0574] Output interface **5604** provides a plurality of output buses and/or ports for outputting signals from digital control module **5600**. These output buses and/or ports include, for example, buses and/or ports for outputting amplitude information signals (used to generate constant envelope signals), bias control signals (Autobias signals), voltage control signals (power supply signals), and output select signals.

[0575] State machine **5606** performs various functions related to the signal generation and/or performance monitoring functions of digital control module **5600**. In an embodiment, state machine **5606** includes a transfer function module, as described in Section 3, for performing signal generation functions. In another embodiment, state machine **5606** includes modules for generating, among other types of signals, bias control signals, power control signals, gain control signals, and phase control signals. In another embodiment, state machine **5606** includes modules for performing error pre-compensation in a feedforward error correction system.

[0576] RAM **5608** and/or NVRAM **5610** are optional components of digital control module **5600**. In embodiments, RAM **5608** and NVRAM **5610** reside externally of digital control module **5600** and may be accessible to digital control module **5600** through data buses connected to digital control module **5600** via input interface **5602**, for example. RAM **5608** and/or NVRAM **5610** may or may not be needed depending on the specific VPA implementation. For example, a VPA implementation employing feedforward techniques for error pre-compensation may require RAM **5608** or NVRAM **5610** to store error tables or functions. On the other hand, a feedback technique for error correction may solely rely on digital logic modules in the state machine and may not require RAM **5608** or NVRAM **5610** storage. Similarly, the amount of RAM **5608** and NVRAM **5610** storage may depend on the specific VPA implementation. Typically, when used, NVRAM **5610** is used for storing data that is not generated in real time and/or that must be retained when power is turned off. This includes, for example, error tables and/or error values such as scalar values and angular values generated in the testing and characterization phase of the VPA system and/or look up tables used by transfer functions modules.

[0577] FIG. **57** illustrates an exemplary digital control module implementation **5700** according to an embodiment of the present invention. Digital control module implementation **5700** illustrates in particular an exemplary input interface **5602** and an exemplary output interface **5604** of an exemplary VPA digital control module **5700**. As will be further described below, signals of the input and output interfaces **5602** and **5604** of VPA digital control module **5700** correlate directly with signals from the analog core of the VPA and/or signals to/from one or more external processors/controllers connected to the VPA. In the example embodiments described in the sections above, the analog core of the VPA was represented by analog circuitry **186** together with PA stage **190**-{**1**, . . . , n} in FIG. **1**E, for example. It is noted that bit widths of data buses and/or signals of the input and output interfaces in FIG. **57** are provided for the purpose of illustration only and are not limiting.

[0578] The input interface **5602** of exemplary digital control module **5700** includes an A/D IN bus **5702**, a digital I/O bus **5704**, and a plurality of control signals **5706**-**5730**. In other digital control module implementations, the input interface **5602** may include more or less data buses, programming buses, and/or control signals.

[0579] A/D IN bus **5702** carries feedback information from the analog core of the VPA to the digital control module **5700**. Feedback information can be used, among other functions, to monitor the output power of the VPA and/or for amplitude and/or phase variations in branches of the VPA. As illustrated in FIG. **57**, an A/D converter **5732** converts from analog to digital feedback information received from the analog core of the VPA (using A/D IN signal **5736**) before sending it on A/D IN bus **5702** to the digital control module **5700**. In an embodiment, the digital control module **5700** controls a clock signal A/D CLK **5734** of the A/D converter **5732**. In another embodiment, the digital control module **5700** controls an input selector to the AID converter **5732** to select between multiple feedback signals at the input of the A/D converter **5732**. In an embodiment, this is performed using A/D Input Selector signals **5738**-**5746**.

[0580] Digital I/O bus **5704** carries data and control signals into and out of the digital control module **5700** from and to one or more processors or controllers that may be connected to the VPA. In an embodiment, some of control signals **5706**-**5730** are used to inform the digital control module **5700** of the type of information to expect on (or that is present on) digital I/O bus **5704**. For example, PC/(I/Q)n signal **5724** indicates to the digital control module **5700** whether power control information or I/Q data is being sent over digital I/O bus **5704**. Similarly, I/Qn signal **5720** indicates to the digital control module **5700** whether I or Q data is being sent over digital I/O bus **5704**.

[0581] Other control signals of the input interface **5602** of the VPA digital control module **5700** include Digital Enable/Disablen **5706**, PRGM/RUNn **5708**, READ/WRITEn **5710**, CLK OUT **5712**, CLK_IN×2 Enable/Disablen **5714**, CLK_IN×4 Enable/Disablen **5716**, CLK_IN **5718**, TX/RXn **5726**, SYNTH PRGM/SYNTH RUNn **5728**, and OUTPUT SEL/LATCHn **5730**.

[0582] Digital Enable/Disablen signal **5706** controls the power-up, reset, and shut down of the VPA. Signals to power-up, reset, or shut down the VPA typically come from a processor connected to the VPA. For example, when used in a cellular phone, a baseband processor or controller of the cellular phone may shut down the VPA in receive mode and enable it in transmit mode.

[0583] PRGM/RUNn signal **5708** indicates to the digital control module **5700** whether it is in programming or in run mode. In programming mode, the digital control module **5700** can be programmed to enable the desired operation of the VPA. For example, memory (RAM **5608**, NVRAM **5610**) bits of the digital control module **5700** can be programmed to indicate the standard to be used (e.g., WCDMA, EDGE, GSM, etc.) for communication. Programming of digital control module **5700** is done using digital I/O bus **5704**.

[0584] In an embodiment, the VPA is programmed and/or re-programmed (partially or completely) after it is installed in (or integrated with) the final product or device employing the VPA. For example, when used in a cellular phone, the VPA can be programmed after the cellular phone is manufactured to provide the cellular phone with new, additional, modified or different features, such as features related to (1) supported waveforms, (2) power control, (3) enhanced efficiency, and/or (4) power-up and power-down profiles. The VPA can also be programmed to remove waveforms or other features as desired by the network provider.

[0585] Programming of the VPA may be payment based. For example, the VPA may be programmed to include features and enhancements selected and purchased by the end-user.

[0586] In an embodiment, the VPA is programmed after the device is manufactured using any well known method or technique, including but not limited to: (1) programming the VPA using the programming interface of the device employing the VPA; (2) programming the VPA by storing programming data on a memory card readable by the device (a SIM card, for example, in the case of a cellular phone); and/or (3) programming the VPA by transferring programming data to the VPA wirelessly by the network provider or other source.

[0587] READ/WRITEn signal **5710** indicates to the digital control module **5700** whether data is to be read from or written to the digital control module storage (RAM **5608** or NVRAM **5610**) via digital I/O bus **5704**. When data is being read out of the digital control module **5700**, CLK OUT signal **5712** indicates timing information for reading from digital I/O bus **5704**.

[0588] CLK_IN signal **5718** provides a reference clock signal to the digital control module **5700**. Typically, the reference clock signal is selected according to the communication standards supported by the VPA. For example, in a dual-mode WCDMA/GSM system, it is desirable that the reference clock signal be a multiple of the WCDMA chip rate (3.84 MHz) and the GSM channel raster (200 KHz), with 19.2 MHz being a popular rate as the least common multiple of both. Further, CLK_IN signal **5718** can be made a multiple of the reference clock signal. In an embodiment, CLK_IN×2 Enable/Disablen **5714**, CLK_IN×4 Enable/Disablen **5716** can be used to indicate to the VPA digital control module **5700** that a multiple of the reference clock is being provided.

[0589] TX/RXn signal **5726** indicates to the digital control module **5700** when the system (e.g., cellular phone) employing the VPA is going into transmit or receive mode. In an embodiment, the digital control module **5700** is notified a short amount of time prior to the system going into transmit mode in order for it to power up the VPA. In another embodiment, the digital control module **5700** is notified when the system is going into receive mode in order for it to enter a sleep mode or to shutdown the VPA.

[0590] SYNTH PRGM/SYNTH RUNn signal **5728** is used to program the synthesizer that provides the reference frequency to the VPA (such as synthesizers **5918** and **5920** shown in FIG. **59**). When SYNTH PRGM **5728** is high, the VPA digital control module **5700** can expect to receive data for programming the synthesizer on digital I/O bus **5704**. Typically, programming of the synthesizer is needed when selecting the VPA transmission frequency. When SYNTH RUN **5728** goes high, the synthesizer is instructed to run. The synthesizer may be integrated with the VPA system or provided as an external component or subsystem.

[0591] OUTPUT SEL/LATCHn signal **5730** is used to select the VPA output to be used for transmission. This may or may not be needed depending on the number of outputs of the VPA. When OUTPUT SEL **5730** goes high, the digital control module **5700** expects to receive data for selecting the output on digital I/O bus **5704**. When LATCH **5730** goes high, the digital control module **5700** ensures that the VPA output used for transmission is held (cannot be changed) for the duration of the current transmit sequence.

[0592] The output interface **5604** of exemplary digital control module **5700** includes a plurality of data buses (**5748**, **5750**, **5752**, **5754**, **5756**, **5758**, **5760**, **5762**, **5764**, and **5766**), a programming bus **5799**, and a plurality of control signals (**5768**, **5770**, **5772**, **5744**, **5776**, **5778**, **5780**, **5782**, **5784**, **5786**, **5788**, **5790**, **5792**, **5794**, **5796**, and **5798**). In other embodiments of digital control module **5700**, the output interface **5604** may have more or less data buses, programming buses, and/or control signals.

[0593] Data buses **5752**, **5754**, **5756**, and **5758** carry digital information from the digital control module **5700** that is used to generate the substantially constant envelope signals in the analog core of the VPA. Note that exemplary digital control module **5700** may be used in a 4-Branch VPA embodiment (see Section 3.1) or a 2-Branch VPA embodiment (see Section 3.3). For example, digital information carried by data buses **5752**, **5754**, **5756**, and **5758** correspond to signals **722**, **724**, **726**, and **728** in the embodiment of FIG. **7**A or signals **1720**, **1722**, **1724**, and **1726** in the embodiment of FIG. **17**, and may be generated by the digital control module **5700** according to equations (5) (for a 4-Branch VPA embodiment) and (18) (for a 2-Branch VPA embodiment). Digital information carried by data buses **5752**, **5754**, **5756**, and **5758** is converted from digital to analog using respective Digital-to-Analog Converters (DACs **01-04**) to generate analog signals **5753**, **5755**, **5757**, and **5759**, respectively. Analog signals **5753**, **5755**, **5757**, and **5759** are input into vector modulators in the analog core of the VPA as will be further described below with reference to the VPA analog core implementations. In an embodiment, DACs **01-04** are controlled and synchronized by a Vector MOD DAC CLK signal **5770** provided by the digital control module. Further, DACs **01-04** are provided the same central reference voltage VREF_D signal **5743**.

[0594] Data buses **5760** and **5762** carry digital information from the digital control module **5700** that is used to generate bias voltage signals for the PA amplification stage and the driver amplification stage of the VPA (see FIG. **52** for illustration of different amplification stages of the VPA). In another embodiments additional control functions such as pre-driver Stage Bias Control is used. Digital information carried by data bus **5760** is converted from digital to analog using DAC_**05** to generate output stage bias signal **5761**. Similarly, digital information carried by data bus **5762** is converted from digital to analog using DAC_**06** to generate driver stage bias signal **5763**. Output stage bias signal **5761** and driver stage bias signal **5763** correspond, for example, to bias signals A and B illustrated in embodiment **5100**H. In an embodiment, DACs **05** and **06** are controlled and synchronized using an Autobias DAC CLK signal **5772**, and are provided the same central reference voltage VREF_E signal **5745**.

[0595] Data buses **5764** and **5766** carry digital information from the digital control module **5700** that is used to generate voltage control signals for the output stage and the driver stage of the VPA. Digital information carried by data bus **5764** is converted from digital to analog using DAC_**07** to generate output stage voltage control signal **5765**. Similarly, digital information carried by data bus **5766** is converted from digital to analog using DAC_**08** to generate driver stage voltage control signal **5767**. Output stage voltage control signal **5765** and driver stage voltage control **5767** are used to generate supply voltages for the output stage and the driver stage, providing a further method for controlling the voltage of the output stage and driver stage of the VPA. In an embodiment, DACs **07** and **08** are controlled and synchronized using a Voltage Control DAC CLK signal **5774**, and are provided the same central reference voltage VREF_F signal **5747**.

[0596] Data buses **5748** and **5750** carry digital information from the digital control module **5700** that is used to generate gain and phase balance control signals. In an embodiment, the gain and phase balance control signals are generated in response to feedback gain and phase information received from the analog core of the VPA on A/D IN bus **5702**. Digital information carried by data bus **5748** is converted from digital to analog using DAC_**09** to generate analog gain balance control signal **5749**. Similarly, digital information carried by data bus **5750** is converted from digital to analog using DAC_**10** to generate analog phase balance control **5751**. Gain and phase balance control signals **5749** and **5751** provide one mechanism for regulating gain and phase in the analog core of the VPA. In an embodiment, DACs **09** and **10** are controlled and synchronized using a Balance DAC CLK signal **5768**, and are provided the same central reference voltage VREF_B **5739**.

[0597] Programming bus **5799** carries digital instructions from the digital control module **5700** that are used to program frequency synthesizer or synthesizers in the analog core of the VPA. In an embodiment, digital instructions carried by programming bus **5799** are generated according to data received on digital I/O bus **5704**, when SYNTH PRGM signal **5728** is high. Digital instructions for programming the frequency synthesizers include instructions for setting the appropriate synthesizer (HI Band or Low Band) to generate a frequency according to the selected communication standard. In an embodiment, programming bus **5799** is a 3-wire programming bus.

[0598] In addition to the data and programming buses described above, the output interface **5604** includes a plurality of control signals.

[0599] In conjunction with programming bus **5799**, used for programming the frequency synthesizers of the analog VPA core, HI Band Enable/Disablen and Low Band Enable/Disablen control signals **5796** and **5798** are generated to control which of a high band frequency synthesizer and a low band frequency synthesizer of the analog VPA core is enabled/disabled.

[0600] Control signals **5738**, **5740**, **5742**, **5744**, and **5746** control an input selector for multiplexing feedback signals from the analog core of the VPA onto A/D IN input signal **5736** of A/D converter **5732**. In an embodiment, control signals **5738**, **5740**, **5744**, and **5746** control the multiplexing of a power output feedback signal, a differential branch amplitude feedback signal, and a differential branch phase feedback signal on A/D IN signal **5736**. Other feedback signals may be available in other embodiments. In an embodiment, the feedback signals are multiplexed according to a pre-determined multiplexing cycle. In another embodiment, certain feedback signals are periodically carried by A/D IN signal **5736**, while others are requested on-demand by the digital control module.

[0601] Output select control signals **5776**, **5778**, **5780**, **5782**, and **5784** are generated by the digital control module **5700** in order to select a VPA output, when the particular VPA implementation supports a plurality of outputs for different frequency bands and/or technology modes. In an embodiment, output select control signals **5776**, **5778**, **5780**, **5782**, and **5782** are generated according to digital control module input signal **5730**. In the example implementation of FIG. **57**, the digital control module **5700** provides five output select control signals for selecting one of five different VPA outputs. In an embodiment, output select control signals **5776**, **5778**, **5780**, **5782**, and **5784** control circuitry within the analog core of the VPA in order to power up circuitry corresponding to the selected VPA output and to power off circuitry corresponding to the remaining unselected VPA outputs. In embodiments, at any time, output select control signals **5776**, **5778**, **5780**, **5782**, and **5784** ensure that circuitry corresponding to a single VPA output are powered up, when the VPA is in transmit mode. A different digital control module embodiment may have more or less output select control signals depending on the particular number of VPA outputs supported by the particular analog core implementation.

[0602] Vector MOD HI Band(s)/Vector MOD Low Band (s)n control signal **5786** is generated by the digital control module **5700** to indicate whether a high band frequency modulation set or a low band frequency modulation set of vector modulators is to be used in the analog core of the VPA. In an embodiment, the high band and the low band vector modulators have different characteristics, allowing each set to be more suitable for a range of modulation frequencies. Control signal **5786** is generated according to the selected output of the VPA. In an embodiment, control signal **5786** controls circuitry within the analog core of the VPA in order to ensure that the selected set of vector modulators is powered up and that the other set(s) of vector modulators are powered off. In another embodiment, control signal **5786** controls circuitry within the analog core of the VPA in order to couple a set of interpolation filters to the selected set of vector modulators.

[0603] 3G HI Band/Normaln control signal **5788** is an optional control signal which may be used, if necessary, to enable the VPA to support the wide range High frequency band. In an embodiment, control signal **5788** may force more current through the output stage circuitry of the analog core and/or modify the output impedance characteristics of the VPA.

[0604] Filter Response **1**/Filter Response **2**n control signal **5790** is an optional control signal which may be used to dynamically change the response of interpolation filters in the analog core of the VPA. This may be needed as the interpolation filters have different optimal responses for different communication standards. For example, the optimal filter response has a 3 dB corner frequency around 5 MHz for WCDMA or EDGE, while this frequency is around 400 KHz for GSM. Accordingly, control signal **5790** allows for optimizing the interpolation filters according to the used communication standard.

[0605] Attenuator control signals **5792** and **5794** are optional control signals which may be used, if necessary, to provide additional output power control features and functions. For example, attenuator control signals **5792** and **5794** could be configured to enable/disable RF attenuators on the output of the VPA. These attenuators may be required based on the specific VPA implementation, which could be fabricated using Silicon, GaAs, or CMOS processes.

[0606] FIG. **58** illustrates another exemplary digital control module **5800** according to an embodiment of the present invention. Exemplary digital control module **5800** is similar in many respects to digital control module **5700**. In particular, both embodiments **5700**, **5800** have the same input interface **5602**, and substantial portions of the output interface (the output interface in FIG. **58** is labeled with reference number **5604'**). The differences between exemplary embodiments **5700** and **5800** relate to the type of feedback information being provided to the digital control module. Specifically, the two embodiments **5700** and **5800** are designed to operate with distinctly different feedback mechanisms for error correction. These mechanisms will be further described below in Section 4.3 with reference to the exemplary analog core implementations.

[0607] Exemplary implementation **5800** includes different input select control signals **5808**, **5810**, and **5812** compared to exemplary implementation **5700**. Input select control signals **5810** and **5812** control whether feedback information is to be received from the high band or the low band analog circuitry of the VPA, depending on which band is in use. Input select control signal I/Qn **5808** controls the multiplexing of I and Q feedback data from the analog core of the VPA. In an embodiment, control signal **5812** allows sequential switching between I data and Q data on A/D IN signal **5736**.

[0608] In further distinction to exemplary embodiment **5700**, exemplary embodiment **5800** include an additional data bus **5802**, which carries digital information from the digital control module **5800** used to generate an automatic gain control signal **5806**. Automatic gain control signal **5806**

is used to control the gain of an amplifier circuit used in the feedback mechanism in the analog core of the VPA. Further description of this component of the feedback mechanism will be provided below. In an embodiment, digital information carried by data bus **5802** is converted from digital to analog by DAC_**11** to generate analog signal **5806**. DAC_**11** is controlled by a clock signal **5804** provided by the digital control module, and is provided VREF_B signal **5739** as a central reference voltage.

[0609] It is noted that exemplary digital control modules **5700** and **5800** illustrate some of the typical input and output digital control module signals that may be used in a digital control module implementation. More or less input and output signals may also be used, as will be appreciated by a person skilled in the art based on the teachings herein, depending on the system in which the VPA is being used and/or the specific VPA analog core to be used with the digital control module. In an embodiment, exemplary digital control module implementations **5700** and **5800** may be used in conjunction with a VPA analog core using feedback only, feedforward only, or both feedback and feedforward error correction. When used in a feedforward only approach, feedback elements and/or signals (e.g., A/D IN **5702**, control signals **5738**, **5740**, **5742**, **5744**, **5746**, gain and phase balance control signals **5749** and **5751**) may be disabled or eliminated. Accordingly, variations of exemplary digital control module implementations **5700** and **5800** are within the scope of embodiments of the present invention.

4.3) VPA Analog Core

[0610] In this section, various exemplary implementations of the VPA analog core will be provided. As will be described below, the various exemplary implementations share a large number of components, circuits, and/or signals, with the main differences relating to the output stage architecture, the adopted error correction feedback mechanism, and/or the actual semiconductor material used in chip fabrication. As will be understood by a person skilled in the art based on the teachings herein, other VPA analog core implementations are also conceivable by interchanging, adding, and/or removing features among the various exemplary implementations described below. Accordingly, embodiments of the present invention are not to be limited to the exemplary implementations described herein.

4.3.1) VPA Analog Core Implementation A

[0611] FIG. **59** illustrates a VPA analog core implementation **5900** according to an embodiment of the present invention. In an embodiment, the input signals of analog core **5900** connect directly or indirectly (through DACs) to output signals from the output interface **5604** of digital control module **5600**. Similarly, feedback signals from analog core **5900** connect directly or indirectly (through DACs) to the input interface of the digital control module **5600**. For illustrative purposes, the analog core **5900** is shown in FIG. **59** as being connected to digital control module **5700**, as indicated by the same numeral signals on both FIG. **57** and FIG. **59**.

[0612] Analog core implementation **5900** is a 2-Branch VPA embodiment. This implementation **5900**, however, can be readily modified to a 4-Branch or a CPCP VPA embodiment, as will be apparent to persons skilled in the art based on the teachings herein.

[0613] At a high level, analog core **5900** includes an input stage for receiving data signals from the digital control module **5700**, a vector modulation stage for generating substantially constant envelope signals, and an amplification output stage for amplifying and outputting the desired VPA output signal. Additionally, analog core **5900** includes power supply circuitry for controlling and delivering power to the different stages of the analog core, optional output stage protection circuitry, and optional circuitry for generating and providing feedback information to the digital control module of the VPA.

[0614] The input stage of VPA analog core **5900** includes an optional interpolation filter bank (**5910**, **5912**, **5914**, and **5916**) and a plurality of switches **5964**, **5966**, **5968**, and **5970**. Interpolation filters **5910**, **5912**, **5914**, and **5916**, which may also serve as anti-aliasing filters, shape the analog outputs **5753**, **5755**, **5757**, and **5759** of DACs **01**-**04** to generate the desired output waveform. In an embodiment, the response of interpolation filters **5910**, **5912**, **5914**, and **5916** is dynamically changed using control signal **5790** from the digital control module **5700**. Digital control module signal **5790** may, for example, control switches within interpolation filters **5910**, **5912**, **5914**, and **5916** to cause a change in active circuitry (enable/disable RC circuitry) within filters **5910**, **5912**, **5914**, and **5916**. This may be needed as interpolation filters **5910**, **5912**, **5914**, and **5916** have different optimal responses for different communication standards. It should be noted that interpolation filters **5910**, **5912**, **5914**,and **5916** can be implemented using digital circuitry such as FIR filters or programmable FIR filters. When implemented digitally, these filters can be included within the VPA system or integrated with a baseband processor.

[0615] Subsequently, the outputs of interpolation filters **5910**, **5912**, **5914**, and **5916** are switched using switches **5964**, **5966**, **5968**, and **5970** to connect to either an upper band path **5964** or a lower band path **5966** of the VPA analog core **5900**. This determination between the upper and lower band paths is usually made by the digital control module **5700** based on the selected frequency range for transmission by the VPA. For example, the lower band path **5966** is used for GSM-**900**, while the upper band path **5964** is used for WCDMA. In an embodiment, switches **5964**, **5966**, **5968**, and **5970** are controlled by Vector MOD HI Band(s)/Vector MOD Low Band(s)n signal **5786**, provided by the digital control module **5700**. Signal **5786** controls the coupling of each of switches **5964**, **5966**, **5968**, and **5970** to respective first or second inputs, thereby controlling the coupling of the outputs of interpolation filters **5910**, **5912**, **5914**, and **5916** to the either the upper path **5964** or lower path **5966** of the VPA analog core **5900**.

[0616] The vector modulation stage of VPA analog core **5900** includes a plurality of vector modulators **5922**, **5924**, **5926**, and **5928**, divided between the upper band path **5964** and the lower band path **5966** of the analog core **5900**. Based on the selected band of operation, either the upper band path vector modulators (**5922**, **5924**) or the lower band path vector modulators (**5926**, **5928**) are active.

[0617] In an embodiment, the operation of vector modulators **5922**, **5924** or **5926**, **5928** is similar to the operation of vector modulators **1750** and **1752** in the embodiment of FIG. **17**, for example. Vector modulators **5922** and **5924** (or **5926** and **5928**) receive input signals **5919**, **5921**, **5923**, and **5925** (**5927**, **5929**, **5931**, and **5933**) from optional interpolation filters **5910**, **5912**, **5914**, and **5916**, respectively. Input signals **5919**, **5921**, **5923**, and **5925** (or **5927**, **5929**, **5931**, and **5933**) include amplitude information that is used to generate the constant envelope signals by the vector modulators. Further, vector modulators **5922** and **5924** (or **5926** and **5928**) receive a HI Band RF_CLK signal **5935** (LOW BAND RF_CLK signal **5937**) from a HI Band(s) Frequency Synthesizer **5918** (Low Band(s) Frequency Synthesizer **5920**). HI Band(s) Frequency Synthesizer **5918** (Low Band (s) Frequency Synthesizer **5920**) are optionally located externally or in the VPA analog core. In an embodiment, HI Band(s) Frequency Synthesizer **5918** (Low Band(s) Frequency Synthesizer **5920**) generates RF frequencies in the upper band range of 1.7-1.98 GHz (lower band range of 824-915 MHz). In another embodiment, HI Band(s) Frequency Synthesizer **5918** and Low Band(s) Frequency Synthesizer **5920** are controlled by digital control module signals **5796** and **5798**, respectively. Signals **5796** and **5798**, for example, power up the appropriate frequency synthesizer according to the selected transmission frequency band, and instruct the selected synthesizer to generate a RF frequency clock according to the selected transmission frequency.

[0618] Vector modulators **5922** and **5924** (or **5926** and **5928**) modulate input signals **5919**, **5921**, **5923**, and **5925** (**5927**, **5929**, **5931**, and **5933**) with HI BAND RF_CLK signal **5935** (LOW BAND RF_CLK signal **5937**). In an embodiment, vector modulators **5922** and **5924** (or **5926** and **5928**) modulate the input signals with appropriately derived and/or phase shifted versions of HI BAND RF_CLK signal **5935** (LOW BAND RF_CLK signal **5937**), and combine the generated modulated signals to generate substantially constant envelope signals **5939** and **5941** (**5943** and **5945**).

[0619] In another embodiment, vector modulators **5922** and **5924** (or **5926** and **5928**) further receive a phase balance control signal **5751** from the VPA digital control module. Phase balance control signal **5751** controls vector modulators **5922** and **5924** (or **5926** and **5928**) to cause a change in phase in constant envelope signals **5939** and **5941** (or **5943** and **5945**), in response to phase feedback information from the analog core. The amplitude and phase feedback mechanism is further discussed below. Optionally, upper band path vector modulators **5922** and **5924** also receive a 3G HI Band/Normaln signal **5788** from the digital control module. Signal **5788** can be used, if necessary, to further support driving the vector modulators at the highest frequencies of the upper band.

[0620] The output stage of VPA analog core **5900** includes a plurality of MISO amplifiers **5930** and **5932**, divided between the upper band path **5964** and the lower band path **5966** of the analog core **5900**. Based on the selected band of operation, either the upper band path MISO amplifier **5930** or the lower band path MISO amplifier **5932** is active.

[0621] In an embodiment, MISO amplifier **5930** (or **5932**) receives substantially constant envelope signals **5939** and **5941** (or **5943** and **5945**) from vector modulators **5922** and **5924** (or **5926** and **5928**). MISO amplifier **5930** (or **5932**) individually amplifies signals **5939** and **5941** (or **5943** and **5945**) to generate amplified signals, and combines the amplified signals to generate output signal **5947** (or **5949**). In an embodiment, MISO amplifier **5930** (or **5932**) combines the amplified signals via direct coupling, as described herein. Other modes of combining the amplified signals according to embodiments of the present invention have been described above in Section 3.

[0622] The output stage of VPA analog core **5900** is capable of supporting multi-band multi-mode VPA operation. As shown in FIG. **59**, the output stage includes two MISO amplifiers **5930** and **5932** for upper band and lower band operation, respectively. In addition, the output of each of the upper band **5964** and the lower band **5966** is further switched between one or more output paths according to the selected transmission mode (e.g., GSM, WCDMA, etc.). Typically, separate output paths are needed for different transmission modes since FDD-based modes (e.g., WCDMA) require the presence of duplexers at the output, while TDD-based modes (e.g., GSM, EDGE) have T/R switched outputs.

[0623] In analog core **5900**, the output **5947** of MISO amplifier **5930** can be coupled to one of three output paths **5954**, **5956**, and **5958**, with each output path **5954**, **5956**, **5958** being the one that is coupled to an antenna (not shown) or connector (not shown) for a particular mode of transmission. Similarly, the output **5949** of MISO amplifier **5932** can be coupled to one of two output paths **5960** and **5962**. In an embodiment, output select signals **5776**, **5778**, **5780**, **5782**, and **5784**, provided by the digital control module, control switches **5942** and **5944** to couple the output of the active MISO amplifier to the appropriate output path, based on the selected transmission mode. It is noted that more or less output paths **5954**, **5956**, **5958**, **5960**, and **5962** may be used.

[0624] Accordingly, with only two MISO amplifiers **5930** and **5932**, analog core **5900** supports multiple different transmission modes. In an embodiment, analog core **5900** allows for using a single MISO amplifier to support GSM, EDGE, WCDMA, and CDMA **2000**. It is clear therefore that one of the advantages of this exemplary VPA analog core according to implementation **5900** is in the reduction in the number of PAs per supported output paths This directly corresponds to a reduction in required chip area for the VPA analog core **5900**.

[0625] In an embodiment, the output stage of analog core **5900** receives optional output stage autobias signal **5761**, driver stage autobias signal **5763**, and gain balance control signal **5749** from the digital control module. Output stage autobias signal **5761** and driver stage autobias signal **5763** may or may not be needed according to the particular type of transistors used in the actual MISO implementation. In an embodiment, output stage autobias signal **5761** and driver stage autobias signal **5763** control the bias of MISO amplification stages to cause a change in the power output and/or the power efficiency of the VPA. Similarly, gain balance control signal **5749** may cause a change in the gain levels of different MISO amplification stages, in response to power output feedback information received by the digital control module from the analog core. Further discussion of these optional output stage input signals will be provided below.

[0626] In an embodiment, the output stage of analog core **5900** provides optional feedback signals to the digital control module **5700** of the VPA. Typically, these feedback signals are used by the digital control module **5700** to correct for amplitude and phase variations in branches of the VPA and/or for controlling the output power of the VPA. In the specific implementation of analog core **5900**, a differential feedback approach is employed to monitor for amplitude and phase variations, using a differential branch amplitude signal **5950** and a differential branch phase signal **5948** provided by the output stage. Further, output power monitoring is provided using signals PWR Detect A **5938** and

PWR Detect B **5940**, which measure the output power of MISO amplifiers **5930** and **5932**, respectively. Since only one of MISO amplifiers **5930** and **5932** can be active at any time, in an embodiment, PWR Detect A **5938** and PWR Detect **5940** are summed together using summer **5942**, to generate a signal that corresponds to the output power of the VPA.

[0627] In an embodiment, the feedback signals from the output stage are multiplexed using an input selector **5946** controlled by the digital control module **5700**. In another embodiment, the digital control module **5700** uses A/D Input Selector signals **5738**, **5740**, **5742**, **5744**, and **5746** to control input selector **5946** and select the feedback signal to be received. It is noted that monitoring of feedback signals may not need to occur in real-time rate and may only need to be performed periodically at a low rate. For example, for the purpose of branch amplitude and phase error correction, the rate at which feedback monitoring is performed depends on several factors such as the degree of feedforward correction being performed in the digital control module, process variations due to temperature, or operation changes such as changing battery or supply voltages.

[0628] Above, the tradeoffs between feedforward and feedback error compensation and/or correction techniques have been described. Accordingly, parameters governing the rates at which feedback monitoring is performed are design choices typically selected by the actual designer of the VPA. As a result, analog core implementation **5900** can be programmed to operate as a pure feedback implementation by disabling any feedforward correction in the digital control module, a pure feedforward implementation by disabling the monitoring of feedback signals, or as a hybrid feedforward/feedback implementation with variable feedforward/feedback utilization.

[0629] In an embodiment, the output stage of analog core **5900** includes optional output stage protection circuitry. In FIG. **59**, this is illustrated using VSWR (Voltage-Standing-Wave-Ratio) Protect circuitry **5934** and **5936** coupled respectively to MISO amplifiers **5930** and **5932**. VSWR protection circuitry **5934**, **5936** may or may not be needed depending on the actual MISO amplifier implementation. In an embodiment, VSWR Protect circuitry **5934** and **5936** protect the output stage PAs (see PAs **6030** and **6032** in FIG. **60**, for example) from going into thermal shutdown or device breakdown, when the output voltage level could cause the output stage breakdown voltage to be exceeded. In conventional systems, this is achieved by using an RF isolator at the output of the PAs, which is both expensive and lossy (typically causes around 1.5 dB in power loss). Accordingly, VSWR Protect circuitry **5934**, **5936** eliminate the need for isolators at the output stage, further reducing the cost, size, and power loss of the VPA. In an embodiment, VSWR Protect circuitry **5934**, **5936** enable an isolator-free output stage capable of supporting WCDMA. VSWR protection circuitry **5934** and **5936** also enable the VPA to operate into any VSWR level without damaging the VPA. VSWR protection circuitry can be designed to deliver the maximum output power of a particular implementation of a VPA into any VSWR level.

[0630] As described above, analog core **5900** includes power supply circuitry for controlling and delivering power to the different stages of the analog core **5900**. In one aspect, the power supply circuitry provides means for powering up active portions of the VPA analog core **5900**. In another aspect, the power supply circuitry provides means for controlling the power efficiency and/or the output power of the VPA.

[0631] In analog core implementation **5900**, the power supply circuitry includes MA Power Supply **5902**, Driver Stage Power Supply **5904**, Output Stage Power Supply **5906**, and Vector Mods Power Supply **5908**. In an embodiment, the power supply circuitry is controlled by output select signals **5776**, **5778**, **5780**, **5782**, and **5784**, provided by the digital control module **5700**.

[0632] MA Power Supply **5902** includes circuitry for controlling the powering up of active portions of the VPA analog core **5900**. In analog core **5900**, MA Power Supply **5902** has two outputs MA**1** VSUPPLY **5903** and MA**2** VSUPPLY **5905**. At any time, only one of MA**1** VSUPPLY **5903** or MA**2** VSUPPLY **5905** is active, ensuring that only the upper band **5964** or the lower band **5966** portion of the VPA analog core **5900** is powered up. In an embodiment, the active output of MA Power Supply **5902** is coupled to all active circuitry of the VPA analog core **5900**, with the exception of circuitry having unique power supply signals as described below. MA Power Supply **5902** receives output select signals from the digital control module, which enable one or the other of output signals MA**1** VSUPPLY **5903** or MA**2** VSUPPLY **5905**, based on the selected output of the VPA.

[0633] Driver Stage Power Supply **5904** includes circuitry for providing power to the driver stage circuitry of the MISO amplifiers **5930**, **5932**. Similar to MA Power Supply **5902**, Driver Stage Power Supply **5904** has two outputs MA**1** Driver VSUPPLY **5907** and MA**2** Driver VSUPPLY **5909**, with only one of the two outputs being active at any time. Driver Stage Power Supply **5904** is also controlled by output select signals **5776**, **5778**, **5780**, **5782**, and **5784** according to the selected output of the VPA. In addition, Driver Stage Power Supply **5904** receives a Driver Stage Voltage Control signal **5767** from the digital control module **5700**. In an embodiment, the outputs MA**1** Driver VSUPPLY **5907** and MA**2** Driver VSUPPLY **5909** are generated according to the received Driver Stage Voltage Control signal **5767**. In another embodiment, Driver Stage Voltage Control signal **5767** causes Driver Stage Power Supply **5904** to increase or decrease MA**1** Driver VSUPPLY **5907** or MA**2** Driver VSUPPLY **5909** to control the driver stage power amplification level. In another embodiment, Driver Stage Voltage Control signal **5767** is used by the digital control module **5700** to affect a change, using Driver Stage Power Supply **5904**, in the power supply voltage of the driver stage of the active MISO amplifier **5930** or **5932**, thereby controlling the power efficiency of the VPA.

[0634] Output Stage Power Supply **5906** includes circuitry for providing power to the PA stage circuitry of the MISO amplifiers **5930**, **5932**. Similar to MA Power Supply **5902**, Output Stage Power Supply **5906** has two outputs MA**1** Output Stage VSUPPLY **5911** and MA**2** Output Stage VSUPPLY **5913**, with only one of the two outputs being active at any time. Output Stage Power Supply **5906** is also controlled by output select signals **5776**, **5778**, **5780**, **5782**, and **5784** according to the selected output of the VPA. In addition, Output Stage Power Supply **5906** receives an Output Stage Voltage Control signal **5765** from the digital control module **5700**. In an embodiment, the outputs MA**1** Output Stage VSUPPLY **5911** and MA**2** Output Stage VSUPPLY **5913** are generated according to the received

Output Stage Voltage Control signal **5765**. In another embodiment, Output Stage Voltage Control signal **5765** causes Output Stage Power Supply **5906** to increase or decrease MA**1** Output Stage VSUPPLY **5911** or MA**2** Output Stage VSUPPLY **5913** to control the PA stage power amplification level. In another embodiment, Output Stage Voltage Control signal **5765** is used by the digital control module **5700** to affect a change, using Output Stage Power Supply **5906**, in the power supply voltage of the PA stage of the active MISO amplifier **5930** or **5932**, thereby controlling the power efficiency of the VPA.

[0635] Vector Mods Power Supply **5908** includes circuitry for providing power to the vector modulators **5922**, **5924**, **5926**, and **5928** of the analog core **5900**. In analog core **5900**, Vector Mods Power Supply **5908** has two outputs **5915** and **5917** for powering up the upper band vector modulators **5922** and **5924** and the lower band vector modulators **5926** and **5928**, respectively. At any time, only one of outputs **5915** or **5917** is active, ensuring that only the upper band or the lower vector modulators of the analog core **5900** are powered up. Vector Mods Power Supply **5908** receives a vector mod select signal **5786** from the digital control module **5700**, which controls which of its two outputs **5915** and **5917** is active, according to the selected transmission frequency requirements.

[0636] In addition to the above described power supply circuitry, analog core **5900** may optionally include voltage reference generator circuitry. The voltage reference generator circuitry may reside externally or within the VPA analog core **5900**. The voltage reference generator circuitry generates reference voltages for different circuits within the VPA. In an embodiment, as illustrated in FIG. **57**, the voltage reference generator circuitry provides reference voltages to DACs **01-10**, coupled to data outputs of the digital control module. In another embodiment, as illustrated in FIG. **59**, the voltage reference generator circuitry provides reference voltages to the interpolation filters and/or the vector modulators in the VPA analog core. In an embodiment, circuits of the same branch of the VPA are provided with the same reference voltage. For example, note that DACs **01** and **02**, interpolation filters **5910** and **5912**, and vector modulators **5922** and **5924**, which represent a VPA branch or data path, all share the same reference voltage VREF_C **5741**. For different implementations and system performance requirements, the voltage reference signals can be provided as a single reference voltage or multiple reference voltages.

[0637] FIG. **60** illustrates an output stage embodiment **6000** according to VPA analog core implementation **5900**. Output stage embodiment **6000** includes a MISO amplifier stage **6058**, an optional output switching stage (embodied by switch **6044**), and optional output stage protection and power detection circuitry.

[0638] In an embodiment, MISO amplifier stage **6058** corresponds to MISO amplifier **5930** in analog core **5900**. Accordingly, MA VSUPPLY signal **6006**, MA Driver VSUPPLY signal **6004**, and MA Output Stage VSUPPLY signal **6002** correspond respectively to signals **5903**, **5907**, and **5911** in FIG. **59**. Similarly, MA IN**1** and MA IN**2** input signals **6008** and **6010** and MA Output signals **6046**, **6048**, and **6050** correspond respectively to MISO input signals **5939** and **5941** and output signals **5954**, **5956**, and **5958** in FIG. **59**. PWR Detect signal **6023** corresponds to PWR Detect A signal **5938** in FIG. **59**. (Generally, implementation of MISO amplifier **5932** could also be based on MISO amplifier stage **6058** in FIG. **60**.)

[0639] MISO amplifier stage **6058** in embodiment **6000** includes a pre-driver amplification stage, embodied by Pre-Drivers **6012** and **6014**, a driver amplification stage, embodied by Drivers **6018** and **6020**, and a PA amplification stage, embodied by output stage PAs **6030** and **6032**. In an embodiment, substantially constant envelope input signals MA IN**1** **6008** and MA IN**2** **6010** are amplified at each stage of MISO amplifier **6058**, before being summed at the outputs of the PA stage.

[0640] In an embodiment, MISO amplifier stage **6058** is powered by power supply signals provided by voltage controlled power supply circuits. As described with reference to FIG. **59**, the power supply signals are generated by power supply circuitry of the VPA analog core **5900**. In an embodiment, the power supply signals are used to control the power supply voltages of the different amplification stages of MISO amplifier stage **6058**, thereby affecting the power efficiency of the VPA under various operating conditions. In another embodiment, the power supply signals are used to control the gain of each of the different amplification stages of MISO amplifier stage **6058**, thereby enabling a power control mechanism. Further, the power supply signals can be controlled independently of each other, allowing for independent control of power and/or efficiency for each of the different amplification stages of MISO amplifier stage **6058**. This independent control allows, for example, for shutting off one or more amplification stages of MISO amplifier **6058** according to the desired output power of the VPA. In FIG. **60**, the power supply signals are illustrated using signals **6002**, **6004**, and **6006**.

[0641] In an embodiment, MISO amplifier stage **6058** includes bias control circuitry. The bias control circuitry may be optional according to the particular MISO amplifier implementation. In an embodiment, the bias control circuitry provides a mechanism for controlling efficiency and/or power at each amplification stage of MISO amplifier **6058**. This mechanism is independent of the mechanism described above with reference to the power supply signals. Further, this mechanism provides for independently and individually controlling each amplification stage. In FIG. **60**, the bias control circuitry is illustrated using Gain Balance Control Circuitry **6016**, Driver Stage Autobias Circuitry **6022**, and Output Stage Autobias Circuitry **6028**.

[0642] In an embodiment, Gain Balance Control Circuitry **6016** is coupled to the inputs of the pre-driver amplification stage as illustrated in FIG. **60**. Gain Balance Control Circuitry **6016** receives a Gain Balance Control signal **5749** from the digital control module **5700** (through a DAC), and outputs input bias control signals **6013** and **6015**. Driver Stage Autobias Circuitry **6022** is coupled to the inputs of the driver amplification stage as illustrated in FIG. **60**. Driver Stage Autobias Circuitry **6022** receives Driver Stage Autobias signal **5763** from the digital control module **5700** (through a DAC), and outputs input bias control signals **6017** and **6019**. Similarly, Output Stage Autobias Circuitry **6028** is coupled to the inputs of the PA amplification stage as illustrated in FIG. **60**. Output Stage Autobias Circuitry **6028** receives Output Stage Autobias signal **5761** from the digital control module **5700** (through a DAC), and outputs input bias control signals **6029** and **6031**.

[0643] In an embodiment, the digital control module **5700** independently controls the bias of the pre-driver stage, the driver stage, and the PA stage of MISO amplifier **6058** using Gain Balance Control signal **5749**, Driver Stage Autobias signal **5763**, and Output Stage Autobias signal **5761**, respectively. In another embodiment, the digital control module **5700** may affect a change in the bias of the pre-driver stage, the driver stage, and/or the PA stage of MISO amplifier **6058** only using Gain Balance Control signal **5749**. As illustrated in FIG. **60**, Gain Balance Control Circuitry **6016** is coupled to Driver Stage Autobias Circuitry **6022** and Output Stage Autobias Circuitry **6028**. In an embodiment, a change in the overall gain of the VPA is affected by digital control module **5700** first by controlling the bias at the pre-driver stage. If further gain change is needed, bias control is performed at the driver stage, and subsequently at the PA stage.

[0644] In an embodiment, MISO amplifier stage **6058** includes circuits for enabling an error correction and/or compensation feedback mechanism. In output stage embodiment **6000**, a differential feedback mechanism is adopted, whereby Differential Branch Amplitude Measurement Circuitry **6024** and Differential Branch Phase Measurement Circuitry **6026** respectively measure differences in amplitude and phase between branches of MISO amplifier **6058**. In an embodiment, Differential Branch Amplitude Measurement Circuitry **6024** and Differential Branch Phase Measurement Circuitry **6026** are coupled at the inputs of the PA stage (PAs **6030** and **6032**) of MISO amplifier **6058**. In other embodiments, circuitry **6024** and **6026** may be coupled at the inputs of prior stages of MISO amplifier **6058**. In an embodiment, Differential Branch Amplitude Measurement Circuitry **6024** and Differential Branch Phase Measurement Circuitry **6026** respectively output Differential Branch Amplitude signal **5950** and Differential Branch Phase signal **5948**, which are fed back to digital control module **5700** (through A/D converters). Since digital control module **5700** knows at any particular time the correct differences in amplitude and/or phase between the branches of MISO amplifier **6058**, it may determine any errors in amplitude and/or phase based on Differential Branch Amplitude signal **5950** and Differential Branch Phase signal **5948**.

[0645] Output stage embodiment **6000** includes optional output stage protection circuitry. The output stage protection circuitry may or may not be needed according to the particular MISO amplifier implementation. In FIG. **60**, the output stage protection circuitry is illustrated using VSWR Protection Circuitry **6034**. In an embodiment, VSWR Protection Circuitry **6034** monitors the output of the PA stage, and controls the gain of MISO amplifier **6058** to protect PAs **6030** and **6032**. In embodiment **6000**, VSWR Protection Circuitry **6034** receives a signal **6036**, which is coupled either directly or indirectly to the output of the PA stage. In an embodiment, VSWR Protection Circuitry **6034** ensures that the voltage level at the output of the PA stage remains below a certain level, to prevent PAs **6030** and **6032** from going into thermal shutdown or experiencing device breakdown. In an embodiment, VSWR Protection Circuitry **6034** ensures that a breakdown voltage of PAs **6030** and **6032** is not exceeded. Accordingly, whenever the voltage level at the output of PAs **6030** and **6032** is above a pre-determined threshold, VSWR Protection Circuitry **6034** may cause a decrease in the gain of the MISO amplification stages. In an embodiment, VSWR Protection Circuitry **6034** is coupled to Balance Gain Control Circuitry **6016**, which in turn is coupled to both Driver Stage Autobias Circuitry **6022** and Output Stage Autobias Circuitry **6028**. In an embodiment, VSWR Protection Circuitry **6034** responds to a pre-determined voltage level at the output stage PAs by decreasing gain first at the pre-driver stage, then at the driver stage, and finally at the PA stage. As described above, VSWR Protection Circuitry **6034** may or may not be needed according to the particular MISO amplifier implementation. For example, a GaAs (Gallium Arsenide) MISO amplifier implementation would not require VSWR Protection Circuitry, as typical breakdown voltages of GaAs transistors are too large to be exceeded in many RF scenarios.

[0646] Output stage embodiment **6000** includes optional power detection circuitry. In an embodiment, the power detection circuitry serves as a means for providing power level feedback to the digital control module. In FIG. **60**, the power detection circuitry is illustrated using Power Detection Circuitry **6038**. In an embodiment, Power Detection Circuitry **6038** is coupled to the output of the PA stage of MISO amplifier **6058**. Power Detection Circuitry **6038** may be coupled directly or indirectly to the output of the PA stage as illustrated by signal **6040** in FIG. **60**. In an embodiment, Power Detection Circuitry **6038** outputs a PWR Detect signal **6023**. PWR Detect signal **6023** may be equivalent to PWR Detect A signal **5938** or PWR Detect B signal **5940** shown in FIG. **59**, which are fed back (through A/D converters) into the digital control module of the VPA. The digital control module uses PWR Detect signal **6023** to regulate the output power of the VPA as desired.

[0647] The optional output switching stage of output stage embodiment **6000** is embodied by a switch **6044** in FIG. **60**. In an embodiment, switch **6044** is coupled to one of three outputs **6046**, **6048**, or **6050** of the VPA. As described earlier, the switch is controlled by a set of output select signals **5776**, **5778**, and **5780**, provided by the digital control module. Switch **6044** is coupled to the proper output according to the select transmission mode and/or desired output frequency requirements (e.g., GSM, WCDMA, etc.).

[0648] Accordingly, pull-up impedance coupling at the output of the VPA can be done in various ways. In an embodiment, as shown in FIG. **60**, pull-up impedances **6052**, **6054**, and **6056** are respectively coupled between outputs **6046**, **6048**, and **6050** and MA Output Stage VSUPPLY **6002**. In another embodiment, a single pull-up impedance is used and is coupled between the output **6042** of the PA stage and MA Output Stage VSUPPLY **6002**. The advantage of the first approach lies in that, by placing the pull-impedance after the switch **6044**, the impedance characteristics of switch **6044** can be taken into account when selecting values for impedances **6052**, **6054**, and/or **6056**, allowing the VPA designer to exploit a further aspect to increase the efficiency of the VPA. On the other hand, the second approach requires a smaller number of pull-up impedances.

[0649] According to the particular MISO amplifier implementation, output stage embodiment **6000** may include more or less circuitry than to what is illustrated in FIG. **60**.

[0650] According to embodiments of the present invention, output stage embodiment **6000** including MISO amplifier stage **6058**, the optional output switching stage (switch **6044**), and the optional output protection and power detection circuitry may be fabricated using a SiGe (Silicon-Germanium) material. In another embodiment, MISO amplifier stage **6058** is fabricated using SiGe, and the output switching stage is fabricated using GaAs. In another embodiment, the PA stage (PAs **6030** and **6032**) and the output switching stage are fabricated using GaAs, while other circuitry of MISO amplifier stage **6058** and optional circuitry of the output stage are fabricated using SiGe. In another embodiment, the PA stage, the driver stage, and the output switching stage are fabricated using GaAs, while other circuitry of MISO amplifier stage **6058** and optional circuitry of the output stage are fabricated using SiGe. In another embodiment, the PA stage, the driver stage, the pre-driver stage, and the output switching stage are fabricated using GaAs. In another embodiment, the VPA system may be implemented using CMOS for all circuitry except for the output stage (**6030** or **6032**) which could be implemented in SiGe or GaAs material. In another embodiment, the VPA system may be implemented in its entirety in CMOS. Other variations and/or combinations of fabrication material(s) used for circuitry of the output stage are also possible, as can be understood by a person skilled in the art, and are therefore also within the scope of embodiments of the present invention.

[0651] Accordingly, as different semiconductor materials have different costs and performance, embodiments of the present invention provide a variety of VPA designs encompassing a wide range of cost and performance options.

4.3.2) VPA Analog Core Implementation B

[0652] FIG. **61** illustrates an alternative VPA analog core implementation **6100** according to an embodiment of the present invention. For illustrative purposes, the VPA analog core **6100** is shown in FIG. **61** as being connected to digital control module **5700**, although alternatively other digital control modules could be used. The physical connection between analog core **6100** and digital control module implementation **5700** is illustrated in FIG. **61**, as indicated by the same numeral signals on both FIG. **57** and FIG. **61**.

[0653] Analog core implementation **6100** is corresponds to a 2-Branch VPA embodiment. This implementation, however, can be readily modified to a 4-Branch or a CPCP VPA embodiment, as will be apparent to persons skilled in the art based on the teachings herein.

[0654] Analog core implementation **6100** has the same input stage and vector modulation stage as analog core implementation **5900**, described above. Accordingly, similar to analog core implementation **5900**, analog core **6100** includes an upper band path **5964** and a lower band path **5966** for upper band and lower band operation of the VPA, respectively.

[0655] One of the differences between analog core **5900** and analog core **6100** lies in the output stage of the VPA. In contrast to the output stage of analog core **5900**, which includes two MISO amplifiers **5930** and **5932**, the output stage of analog core **6100** includes five MISO amplifiers **6126**, **6128**, **6130**, **6132**, and **6134**, divided between the upper band path **5964** and the lower band path **5966** of the analog core. In an embodiment, the output stage includes a combination of SiGe and GaAs MISO amplifiers. In an embodiment, the upper band path **5964** includes three MISO amplifiers **6126**, **6128**, and **6130**, and the lower band path **5966** includes two MISO amplifiers **6132** and **6134**. Based on the selected band of operation, a single MISO amplifier, either in the upper band path **5964** or the lower band path **5966**, is active. In an embodiment, each of MISO amplifiers **6126**, **6128**, **6130**, **6132**, and **6134** can be dedicated to a single transmission mode (e.g., WCDMA, GSM, EDGE, etc.) of the VPA. This is in contrast to analog core **5900**, where each of MISO amplifiers **5930** and **5932** supports more than one transmission modes. Advantages and disadvantages of each architecture will be further discussed below.

[0656] As a result of having more than one MISO amplifiers per path, a switching stage is needed to couple the vector modulation stage to the MISO amplifiers in analog core **6100**. In FIG. **61**, this is illustrated using switches **6118**, **6120**, **6122**, and **6124**. In an embodiment, according to the selected transmission mode, switches **6118** and **6120** couple the outputs **5939** and **5941** of vector modulators **5922** and **5924** to one of MISO amplifiers **6126**, **6128**, and **6130**. Similarly, switches **6122** and **6124** couples the outputs **5943** and **5945** to one of MISO amplifiers **6132** and **6134**, according to the selected transmission mode and/or frequency requirements.

[0657] In an embodiment, MISO amplifier **6126** (or **6128**, **6130**, **6132**, **6134**) receives constant envelope signals **6119** and **6121** (or **6123** and **6125**, **6127** and **6129**, **6131** and **6133**, **6135** and **61137**). MISO amplifier **6126** (or **6128**, **6130**, **6132**, **6134**) individually amplifies signals **6119** and **6121** (or **6123** and **6125**, **6127** and **6129**, **6131** and **6133**, **6135** and **6137**) to generate amplified signals, and combines the amplified signals to generate output signal **6141** (**6144**, **6146**, **6148**, **6150**). In an embodiment, MISO amplifier **6126** (or **6128**, **6130**, **6132**, **6134**) combines the amplified signals via direct coupling, as described herein. Other modes of combining the amplified signals according to embodiments of the present invention have been described above in Section 3.

[0658] The output stage of VPA analog core **6100** is capable of supporting multi-band multi-mode VPA operation. Further, since the output stage of analog core **6100** can dedicate one MISO amplifier for each supported transmission mode, the output switching stage (embodied in analog core **5900** by switches **5942** and **5944**) can be eliminated. This results in a more efficient output stage (no power loss due switching stage), but at the expense of a larger chip area. This summarizes the main tradeoff between the architecture of analog core **5900** and that of analog core **6100**.

[0659] In an embodiment, the output stage of analog core **6100** receives optional bias control signals from digital control module **5700**. These are output stage autobias signal **5761**, driver stage autobias signal **5763**, and gain balance control signal **5749**, which have been described above with reference to analog core **5900**.

[0660] In an embodiment, the output stage of analog core **6100** provides optional feedback signals to digital control module **5700** of the VPA. These feedback signals include Differential Branch Amplitude signal **5950** and Differential Branch Phase signal **5948**, described above with reference to analog core **5900**, to enable a differential feedback approach to monitor for amplitude and phase variations in branches of the VPA. Also, similar to analog core **5900**, output power monitoring is provided using PWR Detect signals **6152**, **6154**, **6156**, **6158**, and **6160**, each of which measuring one of outputs **6142**, **6144**, **6146**, **6148**, and **6150** of the VPA. Since only one of the VPA outputs can be active at any time, PWR Detect signals **6152**, **6154**, **6156**, **6158**, and **6160** are summed together, in an embodiment, using summer **5952**, to generate a signal that corresponds to the current output power of the VPA.

[0661] Similar to analog core **5900**, the feedback signals from the output stage are multiplexed using an input selector **5946** controlled by the digital control module. Other aspects of the multiplexing of the feedback signals are described above with reference to analog core **5900**.

[0662] Similar to analog core **5900**, analog core **6100** can be designed to operate as a pure feedback implementation by disabling any feedforward correction in the digital control module, a pure feedforward implementation by disabling the monitoring of feedback signals, or as a hybrid feedforward/feedback implementation with variable feedforward/feedback utilization.

[0663] In an embodiment, the output stage of analog core **6100** includes optional output stage protection circuitry. In FIG. **61**, this is illustrated using VSWR (Voltage-Standing-Wave-Ratio) Protect circuitry **6136**, **6138**, and **6140** coupled respectively to MISO amplifiers **6128**, **6130**, and **6134**. VSWR protection circuitry may or may not be needed depending on the actual MISO amplifier implementation. For example, note that MISO amplifiers **6126** and **6132**, which are GaAs amplifiers, require no VSWR protection circuitry for many applications. Functions and advantages of VSWR Protection circuitry according to embodiments of the present invention are described above with reference to analog core **5900**.

[0664] Analog core **6100** includes power supply circuitry for controlling and delivering power to the different stages of the analog core. In one aspect, the power supply circuitry provides means for powering up active portions of the VPA analog core. In another aspect, the power supply circuitry provides means for controlling the power efficiency and/or the output power of the VPA.

[0665] The power supply circuitry of analog core **6100** is substantially similar to the power supply circuitry of analog core **5900**, with the difference being that analog core **6100** includes five MISO amplifiers as opposed to two in analog core **5900**. In FIG. **61**, the power supply circuitry is embodied in GMA and MA Power Supply circuitry **6102**, Driver Stage Power Supply circuitry **5904**, Output Stage Power Supply circuitry **5908**, and Vector Mods Power Supply circuitry **5908**. Each of circuitry **6102**, **5904**, and **5906** has five output power supply signals, with a single one of these five output signals being active at any time, according to the active MISO amplifier of the VPA. Function and operation of the power supply circuitry of analog core **6100** are substantially similar to those of the power supply circuitry of analog core **5900**, described above.

[0666] FIG. **62** illustrates an output stage embodiment **6200** according to VPA analog core implementation **6100**. Output stage embodiment **6200** includes a MISO amplifier stage **6220** and optional output stage protection and power detection circuitry.

[0667] MISO amplifiers **6126**, **6128**, **6130**, **6132** and/or **6134** shown in FIG. **61** can be implemented using an amplifier such as MISO amplifier stage **6220**.

[0668] Output stage embodiment **6200** is substantially similar to output stage embodiment **6000** illustrated in FIG. **60**, with the main difference being in the elimination of the output switching stage (embodied by switch **6044** in FIG. **60**) in embodiment **6200**.

[0669] Similar to embodiment **6000**, MISO amplifier stage **6220** in embodiment **6200** includes a pre-driver amplification stage, embodied by Pre-Drivers **6206** and **6208**, a driver amplification stage, embodied by Drivers **6210** and **6212**, and a PA amplification stage, embodied by output stage PAs **6214** and **6216**. In an embodiment, substantially constant envelope input signals MA IN1 **6202** and MA IN **6204** are amplified at each stage of MISO amplifier **6220**, before being summed at the outputs of the PA stage. Input signals MA IN1 **6202** and MA IN **6204** correspond to signals **6123** and **6125** in FIG. **61**, for example.

[0670] In an embodiment, MISO amplifier stage **6220** of output stage embodiment **6200** is powered by power supply signals provided by voltage controlled power supply circuits. In another embodiment, MISO amplifier stage **6220** includes optional bias control circuitry controllable by the digital control module. In another embodiment, MISO amplifier stage **6220** includes circuits for enabling an error correction and/or compensation feedback mechanism. In another embodiment, output stage embodiment **6000** includes optional output stage protection circuitry and power detection circuitry. These aspects (power supply, bias control, error correction, output protection, and power detection) of output stage embodiment **6200** are substantially similar to what have been described above with respect to output stage embodiment **6000**.

[0671] According to embodiments of the present invention, output stage embodiment **6200** may be fabricated using a SiGe (Silicon-Germanium) material including MISO amplifier stage **6220** and the optional output protection and power detection circuitry. In another embodiment, MISO amplifier stage **6220** is fabricated using SiGe in its entirety. In another embodiment, the PA stage (PAs **6214** and **6216**) of MISO amplifier stage **6220** is fabricated using GaAs, while other circuitry of MISO amplifier stage **6220** and optional circuitry of the output stage are fabricated using SiGe. In another embodiment, the PA stage and the driver stage (Drivers **6210** and **6212**) of MISO amplifier stage **6220** are fabricated using GaAs, while other circuitry of MISO amplifier stage **6220** and optional circuitry of the output stage are fabricated using SiGe. In another embodiment, the PA stage, the driver stage, and the pre-driver stage (Pre-Drivers **6206** and **6208**) are fabricated using GaAs. In another embodiment, the VPA system may be implemented using CMOS for all circuitry except for the output stage (**6030** or **6032**) which could be implemented in SiGe or GaAs material. In another embodiment, the VPA system may be implemented in its entirety in CMOS. Other variations and/or combinations of fabrication material(s) used for circuitry of the output stage are also possible, as can be understood by a person skilled in the art, and are therefore also within the scope of embodiments of the present invention. Further, output stages within the same the VPA may be fabricated using different material, as illustrated in FIG. **61** for example, where MISO amplifiers **6128**, **6130**, and **6134** are SiGe amplifiers and MISO amplifiers **6126** and **6132** are GaAs amplifiers (one or more stages of their output stage are GaAs).

4.3.3) VPA Analog Core Implementation C

[0672] FIG. **63** illustrates another VPA analog core implementation **6300** according to an embodiment of the present invention. For illustrative purposes, example analog core **6300** is shown in FIG. **63** as being connected to digital control module **5800**, although other digital control modules could alternatively be used. The physical connection between analog core **6300** and digital control module **5800** is indicated by the same numeral signals on both FIG. **58** and FIG. **63**.

[0673] Analog core implementation **6300** corresponds to a 2-Branch VPA embodiment. This implementation, however, can be readily modified to a 4-Branch or a CPCP VPA embodiment, as will be apparent to a person skilled in the art based on the teachings herein.

[0674] Analog core implementation **6300** includes similar input stage, vector modulation stage, and amplification output stage as analog core **5900** of FIG. **59**. Function, operation and control of these stages is described above with reference to FIG. **59**.

[0675] Similar to analog core **5900**, analog core **6300** includes a feedback error correction and/or compensation mechanism. In contrast to analog core **5900**, however, analog core **6300** employs a receiver-based feedback mechanism, as opposed to a differential feedback mechanism in analog core **5900**. A receiver-based feedback mechanism is one that is based on having a receiver that receives the active output of the VPA, generates I data and Q data from the received output, and feeds back the generated I and Q data to the digital control module. By estimating the delay between the input and the output of the VPA, the feedback I and Q signals can be properly aligned with their corresponding input I and Q signals. In another embodiment, the receiver feedback includes the complex output signal (magnitude and phase polar information) instead of Cartesian I and Q data signals.

[0676] In an embodiment, this is done by coupling a receiver (not shown) at the active output of the VPA (**5947** or **5949**). In FIG. **63**, signals **6302** and **6304** respectively represent upper band and lower band RF inputs into the receiver. Only one of signals **6302** and **6304** can be active at any time, depending on whether the upper band path **5964** or the lower band path **5966** of analog core **6300** is being used. Similarly, the receiver-based feedback mechanism includes an upper band path and a lower band path. In an embodiment, each of the upper band and lower band feedback paths include an Automatic Gain Controller (AGC) (**6306** and **6308**), I/Q sample-and-hold (S/H) circuitry (**6314**, **6316** and **6318**, **6320**), switching circuitry (**6322** and **6324**), and optional interpolation filters (**6326** and **6328**). In an embodiment, a switch **6330**, controlled by the digital control module by means of input select signals **5810** and **5812**, couples either the upper band or the lower band feedback paths to the digital control module. Further, based on the coupled feedback path, digital control module I/Qn Select signal **5808** controls switching circuitry **6322** or **6324** to alternate the coupling of I data and Q data to the digital control module. Other implementations are also possible as can be understood by a person skilled in the art based on the teachings herein.

[0677] In an embodiment, the AGC circuitry is used to allow the receiver to feedback useful I and Q information over a wide dynamic range of VPA output power. For example, output signals **5954**, **5956**, **5958**, **5960**, and **5962** can vary from +35 dBm to −60 dBm in certain cell phone applications. For I and Q data to contain accurate feedback information, the I and Q output of the receiver needs to be scaled to utilize the majority of the input voltage range of the A/Din signal **5736**, independently of the output signal power. Digital Control module **5800** is designed to control the VPA to the required output power, which allows digital control module **5800** to determine an appropriate receiver gain to achieve the proper A/D input voltage which is digitized through A/D **5732**.

[0678] A VPA analog core with a receiver-based feedback mechanism can be implemented as a pure feedback, feedforward, or hybrid feedback/feedforward system. As described above, a pure feedback implementation requires a minimal amount of or no memory (RAM **5608**, NVRAM **5610**) in the digital control module. This may represent one advantage of an analog core implementation according to analog core **6300**, in addition to the elimination of differential feedback measurement circuitry from the analog core. Nonetheless, analog core **6300** can be programmed to operate as a pure feedback implementation by disabling any feedforward correction in digital control module **5800**, a pure feedforward implementation by disabling the monitoring of feedback signals, or as a hybrid feedforward/feedback implementation with variable feedforward/feedback utilization.

[0679] In an embodiment, the output stage of analog core **6300** includes optional output stage protection circuitry. This is not shown in FIG. **63**, but has been described above with respect to analog core implementations **5900** and **6100**. Other aspects of analog core **6300** (bias control, power supply, etc.) are substantially similar to analog core **5900**, and are described above with reference to FIG. **59**.

[0680] FIG. **64** illustrates an output stage embodiment **6400** according to VPA analog core implementation **6300**. Output stage embodiment **6400** includes a MISO amplifier stage **6434** and an output switching stage. In an embodiment, MISO amplifier stage **6434** corresponds to MISO amplifier **5930** and/or **5932**, shown in FIG. **63** (that is, either or both of MISO amplifiers **5930**, **5932** can be implemented using an amplifier such as MISO amplifier stage **6434**).

[0681] Output stage embodiment **6400** is substantially similar to output stage embodiment **6000** illustrated in FIG. **60**, with the main difference being in the elimination of the differential branch measurement circuitry (**6024** and **6026**) due to the use a receiver-based feedback mechanism.

[0682] Similar to embodiment **6000**, MISO amplifier stage **6434** in embodiment **6400** includes a pre-driver amplification stage, embodied by Pre-Drivers **6406** and **6408**, a driver amplification stage, embodied by Drivers **6410** and **6412**, and a PA amplification stage, embodied by output stage PAs **6414** and **6416**. In an embodiment, constant envelope input signals MA IN1 **6402** and MA IN **6404** are amplified at each stage of MISO amplifier stage **6434**, before being summed at the outputs of the PA stage of MISO amplifier stage **6434**.

[0683] In an embodiment, MISO amplifier stage **6434** of output stage embodiment **6400** is powered by power supply signals provided by voltage controlled power supply circuits. In another embodiment, MISO amplifier stage **6434** includes optional bias control circuitry controllable by the digital control module. In another embodiment, output stage embodiment **6400** includes optional output stage protection circuitry (not shown in FIG. **64**). These aspects (power supply, bias control, and output protection) of output stage embodiment **6400** are substantially similar to what have been described above with respect to output stage embodiment **6000**.

[0684] According to embodiments of the present invention, output stage embodiment **6400** may be fabricated using a SiGe (Silicon-Germanium) material including the MISO amplifier stage **6434**, the output switching stage **6420**, and the optional output protection circuitry. In another embodiment, MISO amplifier stage **6434** is fabricated using SiGe, and the output switching stage **6420** is fabricated using GaAs. In another embodiment, the PA stage (PAs **6414** and **6416**) of MISO amplifier stage **6434** and the output switching stage **6420** are fabricated using GaAs, while other circuitry of MISO amplifier stage **6434** and optional circuitry of the output stage are fabricated using SiGe. In another embodiment, the PA stage, the driver stage (Drivers **6410** and **6412**), and the output switching stage **6420** are fabricated using GaAs, while other circuitry of MISO amplifier stage **6434** and optional circuitry of the output stage are fabricated using SiGe. In another embodiment, the PA stage, the driver stage, the pre-driver stage (Pre-drivers **6406** and **6408**), and the output switching stage **6420** are fabricated using GaAs. In another embodiment, the VPA system may be implemented using CMOS for all circuitry except for the output stage (**6030** or **6032**) which could be implemented in SiGe or GaAs material. In another embodiment, the VPA system may be implemented in its entirety in CMOS. Other variations and/or combinations of fabrication material(s) used for circuitry of the output stage are also possible, as can be understood by a person skilled in the art, and are therefore also within the scope of embodiments of the present invention. Further, output stages within the same the VPA may be fabricated using different material, as illustrated in FIG. **61** for example, where MISO amplifiers **6128**, **6130**, and **6134** are SiGe amplifiers and MISO amplifiers **6126** and **6132** are GaAs amplifiers (one or more stages of their output stage are GaAs).

5. Real-Time Amplifier Class Control of VPA Output Stage

[0685] According to embodiments of the present invention, a VPA output stage can be controlled to vary its amplifier class of operation according to changes in its output waveform trajectory. This concept is illustrated in FIG. **65** with reference to an exemplary WCDMA waveform. The graph in FIG. **65** illustrates a timing diagram of a WCDMA output waveform envelope versus the class of operation of the VPA output stage. Note that the output waveform envelope is directly proportional to the output power of the VPA output stage.

[0686] It is noted that the VPA output stage amplifier class traverses from a class S amplifier to a class A amplifier as the output waveform envelope decreases from its maximum value towards zero. At the zero crossing, the VPA output stage operates as a class A amplifier, before switching to higher class amplifier operation as the output waveform envelope increases.

[0687] One important problem overcome by this real-time ability to control the VPA output stage amplifier class of operation is the phase accuracy control problem. With regard to the example shown in FIG. **65**, the phase accuracy control problem lies in the fact that in order to produce high quality waveforms, at any given power level, a 40 dB of output power dynamic range is desirable. However, the phase accuracy required to produce a 40 dB output power dynamic range (around 1.14 degrees or 1.5 picoseconds) is well beyond the tolerance of practical circuits in high volume applications. As will be appreciated, the specific power ranges cited in this paragraph, and elsewhere herein, are provided solely for illustrative purposes, and are not limiting.

[0688] Embodiments according to the present invention solve the phase accuracy control problem by transiting multiple classes of operation based on waveform trajectory so as to maintain the best balance of efficiency versus practical control accuracy for all waveforms. In embodiments, the output power dynamic range of the VPA output stage exceeds 90 dB.

[0689] In an embodiment, at higher instantaneous signal power levels, the amplifier class in operation (class S) is highly efficient and phase accuracy is easily achieved using phase control. At lower instantaneous signal power levels, however, phase control may not be sufficient to achieve the required waveform linearity. This is illustrated in FIG. **66**, which shows a plot of the VPA output power (in dBm) versus the outphasing angle between branches of the VPA. It can be seen that at high power levels, a change in outphasing angle results in a smaller output power change than at lower power levels. Accordingly, phase control provides higher resolution power control at higher power levels than at lower power levels.

[0690] Accordingly, to support high resolution power control at lower power levels, other mechanisms of control are needed in addition to phase control. FIG. **67** illustrates exemplary power control mechanisms according to embodiments of the present invention using an exemplary QPSK waveform. The QPSK constellation is imposed on a unit circle in the complex domain defined by cos(wt) and sin(wt). The constellation space is partitioned between three concentric and non-intersecting regions: an outermost "phase control only" region, a central "phase control, bias control, and amplitude control" region, and an innermost "bias control and amplitude control" region. According to embodiments of the present invention, the outermost, central, and innermost regions define the type of power control to be applied according to the power level of the output waveform. For example, referring to FIG. **67**, at lower power levels (points falling in the innermost region), bias control and amplitude control are used to provide the required waveform linearity. On the other hand, at higher power levels (points falling in the outermost region), phase control (by controlling the outphasing angle) only is sufficient.

[0691] As can be understood by persons skilled in the art, the control regions illustrated in FIG. **67** are provided for purposes of illustration only and are not limiting. Other control regions can be defined according to embodiments of the present invention. Typically, but not exclusively, the boundaries of the control regions are based on the Complementary Cumulative Density Function (CCDF) of the desired output waveform and the sideband performance criteria. Accordingly, the control regions' boundaries change according to the desired output waveform of the VPA.

[0692] In embodiments, the power control mechanisms defined by the different control regions enable the transition of the VPA output stage between different class amplifiers. This is shown in FIG. **68**, which illustrates, side by side, the output stage amplifier class operation versus the output waveform envelope and the control regions imposed on a unit circle. FIG. **69** further shows the output stage current in response to the output waveform envelope. It is noted that the output stage current closely follows the output waveform envelope. In particular, it is noted that the output stage current goes completely to zero when the output waveform envelope undergoes a zero crossing.

[0693] FIG. **70** illustrates the VPA output stage theoretical efficiency versus the output stage current. Note that the output stage current waveform of FIG. **70** corresponds to the one shown in FIG. **69**. In an embodiment, the VPA output stage operates at 100% theoretical efficiency for 98% (or greater) of the time. It is also noted from FIG. **70** the transition of the output stage between different amplifier classes of operation according to changes in the output stage current.

[0694] FIG. **71** illustrates an exemplary VPA according to an embodiment of the present invention. For illustrative purposes, and not purposes of limitation, the exemplary embodiment of FIG. **71** will be used herein to further describe the various control mechanisms that can be used to cause the transitioning of the VPA output stage (illustrated as a MISO amplifier in FIG. **71**) between different amplifier classes of operation.

[0695] The VPA embodiment of FIG. **71** includes a transfer function module, a pair of vector modulators controlled by a frequency reference synthesizer, and a MISO amplifier output stage. The transfer function module receives I and Q data and generates amplitude information that is used by the vector modulators to generate substantially constant envelope signals. The substantially constant envelope signals are amplified and summed in a single operation using the MISO amplifier output stage.

[0696] According to embodiments of the present invention, the MISO amplifier output stage can be caused to transition in real time between different amplifier classes of operation according to changes in output waveform trajectory. In an embodiment, this is achieved by controlling the phases of the constant envelope signals generated by the vector modulators. In another embodiment, amplitudes of the MISO amplifier input signals are controlled using the transfer function. In another embodiment, the MISO amplifier inputs are biased (biasing of the MISO inputs can be done at any amplification stage within the MISO amplifier) using the transfer function to control the MISO amplifier class of operation. In other embodiments, combinations of these control mechanisms (phase, input bias and/or input amplitude) are used to enable the MISO amplifier stage to transition between different amplifier classes of operation.

[0697] FIG. **72** is a process flowchart **100** that illustrates a method for real-time amplifier class control in a power amplifier, according to changes in output waveform trajectory, according to an embodiment of the invention. Process flowchart **100** begins in step **110**, which includes determining an instantaneous power level of a desired output waveform. In an embodiment, the instantaneous power level is determined as a function of the desired output waveform envelope.

[0698] Based on the determined instantaneous power level, step **120** of process flowchart **100** includes determining a desired amplifier class of operation, wherein said amplifier class of operation optimizes the power efficiency and linearity of the power amplifier. In an embodiment, determining the amplifier class of operation depends on the specific type of desired output waveform (e.g., CDMA, GSM, EDGE).

[0699] Step **130** includes controlling the power amplifier to operate according to the determined amplifier class of operation. In an embodiment, the power amplifier is controlled using phase control, bias control, and/or amplitude control methods, as described herein.

[0700] According to process flowchart **100**, the power amplifier is controlled such that it transitions between different amplifier classes of operation according to the instantaneous power level of the desired output waveform. In other embodiments, the power amplifier is controlled such that it transitions between different amplifier classes of operation according the average output power of the desired output waveform. In further embodiments, the power amplifier is controlled such that it transitions between different amplifier classes of operation according to both the instantaneous power level and the average output power of the desired output waveform.

[0701] According to embodiments of the present invention, the power amplifier can be controlled to transition from a class A amplifier to a class S amplifier, while passing through intermediary amplifier classes (AB, B, C, and D).

[0702] Embodiments of the invention control transitioning of the power amplifier(s) to different amplifier classes as follows:

[0703] To achieve a class A amplifier, the drive level and bias of the power amplifier are controlled so that the output current conduction angle is equal to 360 degrees. The conduction angle is defined as the angular portion of a drive cycle in which output current is flowing through the amplifier.

[0704] To achieve a class AB amplifier, the drive level and bias of the power amplifier are controlled so that the output current conduction angle is greater than 180 degrees and less than 360 degrees.

[0705] To achieve a class B amplifier, the drive level and bias of the power amplifier are controlled so that the output current conduction angle is approximately equal to 180 degrees.

[0706] To achieve a class C amplifier, the drive level and bias of the power amplifier are controlled so that the output current conduction angle is less than 180 degrees.

[0707] To achieve a class D amplifier, the drive level and bias of the power amplifier are controlled so that the amplifier is operated in switch mode (on/off).

[0708] To achieve a class S amplifier, the amplifier is controlled to generate a Pulse Width Modulated (PWM) output signal.

[0709] In an embodiment, the above described real-time amplifier class control of the VPA output stage is accompanied by a dynamic change in the transfer function being implemented in the digital control module of the VPA. This is further described below with respect to FIGS. **73-77**.

[0710] FIG. **73** illustrates an example VPA output stage according to an npn implementation with two branches. Each branch of the VPA output stage receives a respective substantially constant envelope signal. The substantially constant envelope signals are illustrated as IN**1** and IN**2** in FIG. **73**. Transistors of the VPA output stage are coupled together by their emitter nodes to form an output node of the VPA.

[0711] When the VPA output stage operates as a class S amplifier, it effectuates Pulse Width Modulation (PWM) on the received substantially constant envelope signals IN**1** and IN**2**. A theoretical equivalent circuit of the VPA output stage in this amplifier class of operation is illustrated in FIG. **74**. Note that transistors of the VPA output stage are equivalent to switching amplifiers in this class of operation. The output of the VPA as a function of the outphasing angle θ between the substantially constant envelope signals IN**1** and IN**2** (assuming that IN**1** and IN**2** have substantially equal amplitude of value A) is given by

$$SQ(\theta) = A\frac{\pi - \theta}{2\pi}.$$

A plot of this function, described previously as the magnitude to phase shift transform, is illustrated in FIG. 76.

[0712] On the other hand, when the VPA output stage operates as a class A amplifier, it emulates a perfect summing node. A theoretical, equivalent circuit of the VPA output stage in this amplifier class of operation is illustrated in FIG. **75**. Note that transistors of the VPA output stage are equivalent to current sources in this class of operation. The output of the VPA as function of the outphasing angle θ between the substantially constant envelope signals IN**1** and IN**2** (assuming that IN**1** and IN**2** have substantially equal amplitude of value A) is given by $R(\theta)=AA\sqrt{2(1+\cos(\theta))}$. A plot of this function, described previously as the magnitude to phase shift transform, is illustrated in FIG. **76**.

[0713] According to an embodiment of the present invention, amplifier classes of operation A and S represent two extremes of the amplifier operating range of the VPA output stage. However, as described above, the VPA output stage may transition a plurality of other amplifier classes of operation including, for example, classes AB, B, C, and D. Accordingly, the transfer function implemented by the digital control module of the VPA varies within a spectrum of magnitude to phase shift transform functions, with the transform functions illustrated in FIG. **76** representing the boundaries of this spectrum. This is shown in FIG. **77**, which illustrates a spectrum of magnitude to phase shift transform functions corresponding to a range of amplifier classes of operation of the VPA output stage. FIG. **77** illustrates 6 functions corresponding to the six amplifier classes of operation A, AB, B, C, D, and S. In general, however, an infinite number of functions can be generated using the functions corresponding to the two extreme classes of operation A and S. In an embodiment, this is performed using a weighted sum of the two functions and is given by $(1-K)\times R(\theta)+K\times SQ(\theta)$, with $0\leqq K\leqq 1$.

6. Summary

[0714] Mathematical basis for a new concept related to processing signals to provide power amplification and up-conversion is provided herein. These new concepts permit arbitrary waveforms to be constructed from sums of waveforms which are substantially constant envelope in nature. Desired output signals and waveforms may be constructed from substantially constant envelope constituent signals which can be created from the knowledge of the complex envelope of the desired output signal. Constituent signals are summed using new, unique, and novel techniques not available commercially, not taught or found in literature or related art. Furthermore, the blend of various techniques and circuits provided in the disclosure provide unique aspects of the invention which permits superior linearity, power added efficiency, monolithic implementation and low cost when compared to current offerings. In addition, embodiments of the invention are inherently less sensitive to process and temperature variations. Certain embodiments include the use of multiple input single output amplifiers described herein.

[0715] Embodiments of the invention can be implemented by a blend of hardware, software and firmware. Both digital and analog techniques can be used with or without microprocessors and DSP's.

[0716] Embodiments of the invention can be implemented for communications systems and electronics in general. In addition, and without limitation, mechanics, electro mechanics, electro optics, and fluid mechanics can make use of the same principles for efficiently amplifying and transducing signals.

7. Conclusion

[0717] The present invention has been described above with the aid of functional building blocks illustrating the performance of specified functions and relationships thereof. The boundaries of these functional building blocks have been arbitrarily defined herein for the convenience of the description. Alternate boundaries can be defined so long as the specified functions and relationships thereof are appropriately performed. Any such alternate boundaries are thus within the scope and spirit of the claimed invention. One skilled in the art will recognize that these functional building blocks can be implemented by discrete components, application specific integrated circuits, processors executing appropriate software and the like and combinations thereof.

[0718] While various embodiments of the present invention have been described above, it should be understood that they have been presented by way of example only, and not limitation. Thus, the breadth and scope of the present invention should not be limited by any of the above-described exemplary embodiments, but should be defined only in accordance with the following claims and their equivalents.

1. A method of power transmission, modulation, and amplification including output waveform distortion compensation, comprising:

receiving a frequency reference signal;

receiving information;

generating a plurality of control signals from said received information;

generating a plurality of substantially constant envelope signals using said frequency reference signal and said control signals;

amplifying and combining said substantially constant envelope signals to create an output signal; and

reducing waveform distortion in said output signal by reducing phase and amplitude errors in said output signal relative to a desired output signal.

2. The method according to claim **1**, wherein said reducing waveform distortion step comprises:

generating phase and amplitude error values in said output signal relative to said desired output signal.

3. The method according to claim **2**, wherein said step of generating phase and amplitude error values comprises one or more of:

measuring said phase and amplitude error values in said output signal relative to said desired output signal;

calculating said phase and amplitude error values in said output signal relative to said desired output signal; and

estimating said phase and amplitude error values in said output signal relative to said desired output signal.

4. The method according to claim **1**, wherein said reducing waveform distortion step comprises reducing phase and amplitude errors in said output signal due to one or more of:

(a) circuitry process variations;
(b) circuitry temperature variations;
(c) IC package variations;
(d) circuit board variations;
(e) said step of generating a plurality of control signals;
(f) said step of generating a plurality of substantially constant envelope signals;
(g) amplifying said substantially constant envelope signals; and
(h) combining said amplified substantially constant envelope signals at a single power amplifier node.

5. The method according to claim **4**, wherein phase and amplitude errors due to one or more of (a)-(h) are estimated at system manufacture time.

6. The method according to claim **4**, wherein phase and amplitude errors due to one or more of (a)-(h) are at least one of measured, calculated, and estimated during real-time system operation.

7. The method according to claim **4**, wherein said phase and amplitude errors due to (e) are caused by vector modulation circuitry that performs said step of generating a plurality of substantially constant envelope signals.

8. The method according to claim **4**, wherein said phase and amplitude errors due to (g) result in gain and phase imbalances between power amplifier branches.

9. The method according to claim **1**, wherein said reducing waveform distortion step is performed when output waveform distortion at least satisfies system design requirements.

10. The method according to claim **1**, wherein said reducing waveform distortion step is performed to ensure that phase and amplitude errors in said output signal remain within a specified system error tolerance.

11. The method according to claim **1**, wherein said reducing waveform distortion step is performed by pre-compensating for said phase and amplitude errors in said output signal relative to said desired output signal.

12. The method according to claim **3**, wherein said reducing waveform distortion step comprises feedforward error compensation that includes pre-compensating for said estimated phase and amplitude error values in said output signal.

13. The method according to claim **3**, wherein said reducing waveform distortion step comprises feedback error correction that includes correcting for said measured/calculated phase and amplitude error values in said output signal.

14. The method according to claim **3**, wherein said reducing waveform distortion step comprises hybrid feedforward/feedback error compensation that includes at least one of pre-compensating for estimated phase and amplitude error values in said output signal and correcting for measured/calculated phase and amplitude error values in said output signal.

15. The method according to claim **1**, wherein said reducing waveform distortion step comprises adjusting transfer functions that are used to generate said plurality of control signals.

16. The method according to claim **15**, wherein said transfer functions are implemented in a digital control module.

17. The method according to claim **1**, wherein said reducing waveform distortion step comprises adjusting control inputs used to generate said plurality of substantially constant envelope signals.

18. The method according to claim **17**, wherein said control inputs comprise control voltages of vector modulation circuitry that generate said substantially constant envelope signals.

19. The method according to claim **1**, wherein said reducing waveform distortion step comprises applying error pre-compensation to said received information.

20. The method according to claim **19**, further comprising:

generating expected phase and amplitude error values in said output signal; and
adjusting said received information to correct for said generated expected phase and amplitude error values.

21. The method according to claim **20**, further comprising:

generating an error table or function, said error table or function defining expected phase and amplitude errors for a representative range of said received information.

22. The method according to claim **19**, wherein said step of generating expected phase and amplitude error values is performed during a system test and characterization process.

23. An apparatus for power transmission, modulation, and amplification, comprising:

input circuitry that receives information, and that generates a plurality of control signals from said received information;
vector modulation circuitry, coupled to said input circuitry, that receives said control signals and a frequency reference signal, and that generates a plurality of substantially constant envelope signals using said frequency reference signal and said control signals;
a power amplifier that receives said substantially constant envelope signals and amplifies and combines said substantially constant envelope signals to create an output signal; and
means for reducing waveform distortion in said output signal by reducing phase and amplitude errors in said output signal relative to a desired output signal.

24. The apparatus of claim **23**, wherein said means for reducing waveform distortion comprises:

means for generating phase and amplitude error values in said output signal relative to said desired output signal.

25. The apparatus of claim **24**, wherein said means for generating phase and amplitude error values comprises one or more of:

means for measuring said phase and amplitude error values in said output signal relative to said desired output signal;
means for calculating said phase and amplitude error values in said output signal relative to said desired output signal; and
means for estimating said phase and amplitude error values in said output signal relative to said desired output signal.

26. The apparatus of claim **23**, wherein said means for reducing waveform distortion comprises means for reducing phase and amplitude errors in said output signal due to one or more of:

(a) circuitry process variations;
(b) circuitry temperature variations;
(c) IC package variations;
(d) circuit board variations;
(e) said input circuitry;
(f) said vector modulation circuitry;
(g) said power amplifier;
(h) amplifying said substantially constant envelope signals using said power amplifier; and
(i) combining outputs of said power amplifier at a single circuit node of said power amplifier.

27. The apparatus of claim **26**, further comprising:
means for estimating phase and amplitude errors due to one or more of (a)-(i), at system manufacture time.

28. The apparatus of claim **26**, further comprising:
means for at least one of measuring, calculating, and estimating phase and amplitude errors due to one or more of (a)-(i), during real-time system operation.

29. The apparatus of claim **26**, further comprising:
means for reducing gain and phase imbalances between branches of said power amplifier.

30. The apparatus of claim **23**, further comprising:
means for monitoring said phase and amplitude errors in said output signal relative to said desired output signal; and
means for triggering said means for reducing waveform distortion when said phase and amplitude errors at least satisfy system design requirements.

31. The apparatus of claim **30**, wherein said means for monitoring said phase and amplitude errors comprises differential branch phase and differential branch amplitude measurement circuitry.

32. The apparatus of claim **23**, wherein said means for reducing waveform distortion comprises means for pre-compensating for said phase and amplitude errors in said output signal relative to said desired output signal.

33. The apparatus of claim **25**, further comprising:
a feedforward error compensation module configured to pre-compensate for said estimated phase and amplitude error values in said output signal.

34. The apparatus of claim **25**, further comprising:
a feedback error compensation module configured to correct for said measured/calculated phase and amplitude error values in said output signal.

35. The apparatus of claim **25**, further comprising:
a hybrid feedforward/feedback error compensation module configured to compensate for said estimated phase and amplitude error values and to correct for said measured/calculated phase and amplitude error values.

36. The apparatus of claim **23**, wherein said means for reducing waveform distortion comprises means for adjusting transfer functions of a digital control module of said input circuitry.

37. The apparatus of claim **23**, wherein said means for reducing waveform distortion comprises means for adjusting said control signals according to said phase and amplitude errors.

38. The apparatus of claim **23**, wherein said means for reducing waveform distortion comprises means for adjusting control inputs of said vector modulation circuitry.

39. The apparatus of claim **23**, wherein said means for reducing waveform distortion comprises means for applying offset voltages to said vector modulation circuitry.

40. The apparatus of claim **23**, wherein said means for reducing waveform distortion comprises means for pre-compensating said received information for said phase and amplitude errors.

41. The apparatus of claim **40**, wherein said means for pre-compensating said received information comprises:
means for generating expected phase and amplitude error values in said output signal; and
means for adjusting said received information to correct for said expected phase and amplitude error values.

42. The apparatus of claim **41**, wherein said means for pre-compensating said received information further comprises:
an error table or function, wherein said error table or function defines expected phase and amplitude errors for a representative range of said received information.

RELATED APPLICATIONS

[0001] This application is a continuation-in-part of U.S. application Ser. No. 11/302,709, filed Dec. 13, 2005, which is incorporated by reference herein in its entirety. This application claims priority to U.S. Provisional Application No. 60/758,847, filed Jan. 13, 2006; U.S. Provisional Application No. 60/761,822, filed Jan. 24, 2006; U.S. Provisional Application No. 60/784,537, filed Mar. 21, 2006; U.S. Provisional Application No. 60/803,059, filed May 24, 2006; and U.S. Provisional Application No. 60/805,676, filed Jun. 23, 2006, all of which are incorporated by reference herein in their entirety.

BACKGROUND

[0002] Since the late-nineteenth century the use of, and uses for, electricity has increased tremendously, becoming a fundamental part of everyday life for most people. One only has to look at remote parts of the world to see how drastically different life is without electricity. Most electric devices in use today typically draw between a few milliwatts to several megawatts of power, depending on the application. Higher costs for the fuels needed to generate electricity, and a higher electrical demand in general, however, have led to increased electricity costs, thereby increasing the attractiveness of alternative power sources.

[0003] One typical use of electricity is a light emitting diode (LED). LEDs have seen increasing popularity in recent times due to a lower per unit cost and a greater number of available colors. LEDs are more energy efficient (i.e., less power is consumed) and generally have a much longer life expectancy than conventional filament-based light bulbs. In general, LEDs draw approximately 20 mA at 2V (i.e., 40 mW) when illuminated, which is far less than conventional light bulbs.

[0004] Distribution of electricity from a generation plant to the end-user is not a trivial problem. Thousands of miles of wires and cables creating a transmission network are involved in delivering power to consumers. The transmission network adds costs such as material costs and the cost of lost energy due to the resistance of the transmission wires. For the average consumer of electricity, the transmission costs generally equal the cost of the electricity itself. Furthermore, portions of the world have no electricity because it is simply too far from the nearest transmission line or the terrain itself prohibits installation of transmission lines.

SUMMARY

[0005] A method for drawing electricity from a non-animal organism, the method including coupling a first electrical conductor to the non-animal organism, coupling a second electrical conductor to a ground rod, embedding the ground rod into soil at a predetermined depth as a function of a desired current level, whereby the current available from the non-animal organism is increased by increasing the depth that the ground rod is embedded into the soil, coupling an electrical load between the first electrical conductor and the second electrical conductor, the electrical load being configured to draw electricity from the non-animal organism via the first electrical conductor, and operating the electrical load using electricity drawn from the non-animal organism.

[0006] In general, in another aspect, the invention provides a system including a non-animal organism, a first electrical conductor electrically coupled to the non-animal organism, a plurality of ground rods embedded into soil wherein a quantity of the plurality of ground rods is a function of a desired current level from the non-animal organism, whereby the current available from the non-animal organism is increased by increasing the quantity of the plurality of ground rods, a second electrical conductor coupled to the plurality of ground rods, and an electrical load coupled between the first electrical conductor and the second electrical conductor to draw electricity from the non-animal organism, the electrical load using electricity drawn from the non-animal organism.

[0007] In general, in another aspect, the invention provides a method of predicting weather using electricity from a non-animal organism, the method including coupling a first electrical conductor to the non-animal organism, coupling a second electrical conductor to a ground, coupling a voltmeter between the first electrical conductor and the second electrical conductor, measuring a voltage potential between the first and second electrical connectors, providing a weather prediction as a function of the measured voltage potential.

[0008] Implementations of the invention may further include the following features. The method of predicting weather including determining a baseline voltage reading for the non-animal organism under a first weather condition, determining a plurality of voltage readings over time, comparing each of the plurality of voltage readings to the baseline voltage reading to determine differences between the baseline voltage reading and each of the plurality of voltage readings, and calculating information indicative of a second, future weather condition as a function of the differences.

[0009] In general, in another aspect, the invention provides a system for use with live vegetative matter growing in soil, the system including a non-animal organism, a first electrical conductor electrically coupled to the non-animal organism, and a second electrical conductor coupled to the first electrical conductor and coupled to the live vegetative matter, the second electrical conductor providing electricity from the non-animal organism to the live vegetative matter, wherein the growth of the live vegetative matter is stimulated by the electricity provided by the non-animal organism.

[0010] In general, in another aspect, the invention provides a system including a non-animal organism, a first electrical conductor electrically coupled to the non-animal organism, a second electrical conductor coupled to a ground, and an electrical load coupled between the first electrical conductor and the second electrical conductor to draw electricity from the non-animal organism, the electrical load using electricity drawn from the non-animal organism, wherein the load is one of a battery, a battery charging circuit, a sensor, a radio frequency identification chip, a transmitter, a receiver, a global positioning service (GPS) device, a light emitting device, and a fire ignition system.

[0011] Implementations of the invention may include one or more of the following features. The load is the sensor and the sensor is one of an oxygen sensor, an air-speed sensor, a humidity sensor, a barometric pressure sensor, a camera, a photoelectric sensor, an altitude sensor, a smoke detector, a microphone, and a vibration sensor. The load is the GPS device and the GPS device is one of a GPS receiver, a GPS transmitter, a GPS guidance system, and a GPS navigation system. The load is the light emitting device and the light emitting device is one of a light emitting diode configured to emit visible light, and an infrared light emitting diode configured to emit an infrared signal.

[0012] Various aspects of the invention may provide one or more of the following capabilities. A non-animal organism, such as a member of the plant and/or fungi kingdom, may supply electricity to a load. Electricity may be available in remote areas without an electricity transmission network. Alternative "clean" electricity can be produced. An LED may be powered from a non-animal organism. Infra-red LEDs used in military operations may be powered. A traffic light may be powered from a non-animal organism. A security light may be powered from a non-animal organism. Dependence on fossil fuels to generate electricity may be reduced. Lighting may be provided at campgrounds and/or ski areas using power provided from non-animal organisms. Power derived from non-animal organisms may be used to recharge batteries in hybrid vehicles. Advance storm warning can be obtained by measuring the voltage provided by the non-animal organism.

[0013] These and other capabilities of the invention, along with the invention itself, will be more fully understood after a review of the following figures, detailed description, and claims.

BRIEF DESCRIPTION OF THE FIGURES

[0014] FIG. **1** is a diagram of an apparatus for drawing power from a tree.

[0015] FIG. **2** is a diagram of a charging circuit used to provide power derived from a tree to a load.

[0016] FIG. **3** is a flowchart of a process for deriving power from a tree using the charging circuit shown in FIG. **2**.

[0017] FIG. **4** is a circuit diagram of a filtered charging circuit used in providing electricity from a tree to a load, including the charging circuit of FIG. **2** and a filter.

[0018] FIG. **5** is a flowchart of a process of deriving power from a tree using the electrical circuit shown in FIG. **4**.

[0019] FIG. **6** is a circuit diagram of a filtered charging circuit used in providing electricity from a tree to a load and including a battery.

[0020] FIG. **7** is a flowchart of a process of deriving power from a tree using the electrical circuit shown in FIG. **6**.

[0021] FIG. **8** is a flowchart of a process of determining storm distance and/or severity using voltage measurements taken from a tree.

DETAILED DESCRIPTION

[0022] Embodiments of the invention provide techniques for drawing electricity from non-animal organisms such as members of the plant and/or fungi kingdom, and providing the electricity to a load. Non-animal, non-mammal organisms such as spermatophytes, pteridophytes, succulents, Marattiales ferns, Ophioglossales ferns, Leptosporangiate ferns, Mycophycota fungi, Zygomycota fungi, Basidiomycota fungi, and Ascomycota fungi may be used. Specifically, electricity can be drawn from vegetative matter such as a living tree. The amount of available electricity has been found to depend on the location and type of non-animal organism, and to be approximately 0.5-2 volts DC, plus some AC current. For example, an apparatus for using this energy includes a conductor inserted into a tree and connected to a positive terminal of a load. A negative conductor of the load is connected to a grounded conductor, thereby completing a circuit. Other circuitry, such as charging circuits and/or voltage step-up circuits, may also be used. Other embodiments are within the scope of the invention.

[0023] Referring to FIG. **1**, an apparatus **1** for deriving electricity from a tree **25** includes a tap **5**, a conductor **10**, wires **15**, **20**, and **25**, a circuit **30**, and a load **35**. The tap **5** is configured to attach to, and to conduct current flow from, the tree **25**. For example, the tap **5** may be configured to be inserted into the tree **25**, although other configurations are possible (e.g., a non-invasive transformer core that surrounds the circumference of the tree **25**). The wire **15** is electrically coupled to the tap **5** and the circuit **30**. The wire **20** is electrically coupled to the circuit **30** and the load **35**. The wire **25** is electrically coupled to the load **35** and the conductor **10**. The conductor **10** is electrically conductive and is configured to be inserted approximately two feet into the ground while protruding above the ground, although the conductor **10** may be configured to be inserted to other depths. By increasing the depth that the conductor **10** is inserted into the ground and/or using multiple conductors **10**, the load **35** can draw more current from the tree **25**. The conductor **10** is preferably a tinned copper rod. Other materials and/or configurations of the conductor **10** are possible. For example the conductor **10** may be aluminum and/or connected to a "ground" connection of a typical household electrical system. The circuit **30** is electrically conductive and is configured to filter the power provided by the tree, to step-up (or step-down) the voltage supplied by the tree **25**, and/or to store the power provided by the tree **25**. The circuit **30** may perform functions other than those listed above. Also, embodiments of the apparatus **1** without the circuit **30** are possible (e.g., connecting a load directly between the tree **25** and the conductor **10**).

[0024] The load **35** can be any of a number of different devices used for a variety of purposes. For example, the load **35** can include a lithium battery that is charged by the tree **25**, a sensor (e.g., capable of sensing temperature, air speed, humidity, barometric pressure, video, audio, light, vibration, altitude, oxygen levels), a remote sensor (e.g., over a LAN, WAN, the Internet, WiFi), a radio frequency identification (RFID) chip, a transmitter, and/or a receiver. The load **35** can be a device for use with a global positioning system (GPS) such as a GPS receiver, a GPS transmitter, a GPS guidance system, and/or a GPS navigation system. The load **35** can include a fire and/or smoke detection system, a system configured to charge a battery powered device (e.g., a mobile phone, a laptop computer, a portable GPS system, a flashlight, a radio), a lighting system (e.g., for recreational use, for military use)(including, e.g., one or more light emitting diodes (LEDs) such as infrared LEDs), a fire ignition system (e.g., for campground use), a weather detection and/or monitoring system, an emergency alert/assistance beacon, a solar lighting backup system, and/or a wireless transmission system for use with a computer. The load **35** can include a plant (e.g., as described below in Experiment 4).

[0025] Various embodiments of the tap **5** are possible. Preferably, the tap **5** is a stainless steel rod, e.g., a nail, having an outside diameter of about 0.125 inches, but other materials and sizes are possible. For example, brass plated or aluminum rods having an outside diameter of about 0.06 inches may be used. The tap **5** is electrically conductive material and is preferably of a material (e.g., stainless steel) that has a relatively high corrosion resistance, thus inhibiting increased resistance caused by corrosion. For extended use, the tap **5** is preferably not copper (at least on its exterior) as this can negatively affect (e.g., kill) many types of trees. The tap **5** is preferably configured to be inserted between about 0.375 inches and about 0.75 inches into the tree **25**, although other depths are possible. In trees with thick bark, the tap **5** may be inserted further into the tree **25**. For example, if a tree has bark 1 inch thick, the tap **5** may be inserted about 1.5 inches into the tree **25**. The tap **5** is preferably inserted into the tree **25** between about one and about six feet above ground level, although other heights may be used. While the apparatus **1** includes the one tap **5**, multiple taps may be used. Using multiple taps in a single tree has been found to increase the amount of current available from the tree. The taps may all be the same, or one or more taps may be different (e.g., a different material, configured for different insertion depth, etc.) than another tap.

[0026] Referring also to FIG. **2**, an exemplary embodiment **40** of the apparatus **1** including an LED load **115**, and an exemplary circuit **30** that is a charging circuit **50**, which includes switches **55**, **60**, **65**, **70**, **75**, **80**, and **85**, and capacitors **90**, **95**, **100**, and **105**. The switches **55**, **60**, **65**, **70**, **75**, **80**, and **85** are single-pole double-throw (SPDT) switches. The switch **55** includes selective connections **56** and **57**. The switch **57** is connected on one side to the switch **56** and the capacitor **90** and on its other side to an output **125** configured to be connected to the load **115**. The switch **60** also includes selective connections **61** and **62**. When the switches **55** and **60** are in a first state, the connections **56** and **61** are closed and the connections **57** and **62** are open, thereby coupling the capacitor **90** between a power source **110** (here, a tree) and a ground **120**. When the switches **55** and **60** are in a second state, the connections **56** and **61** are open, and the connections **57** and **62** are closed, thereby coupling the capacitor **90** between the load LED **115**, and the switch **65**. Each of the switches **55**, **65**, **75**, and **85** are coupled to the tree **110** via the tap **107**. The switches **65**, **70**, **75**, **80**, and **85** operate as described with respect to the switches **55** and **60**.

[0027] The capacitors **90**, **95**, **100**, and **105** are coupled to the switches **55**, **60**, **65**, **70**, **75**, **80**, and **85** such that when the switches **55**, **60**, **65**, **70**, **75**, **80**, and **85** are in a first state, the circuit **50** is in a charging state and each of the capacitors **90**, **95**, **100**, and **105** are coupled between the power source **110** and the ground **120**. When the switches **55**, **60**, **65**, **70**, **75**, **80**, and **85** are in the first state the capacitors **90**, **95**, **100**, and **105** accumulate an electrical charge. The capacitors **90**, **95**, **100**, and **105** are further coupled to the switches **55**, **60**, **65**, **70**, **75**, **80**, and **85** such that when the switches **55**, **60**, **65**, **70**, **75**, **80**, and **85** are in a second state, the circuit **50** is in a discharging state and the capacitors **90**, **95**, **100**, and **105** are coupled in series between the ground **120** and a load **115** thus providing power to the load **115**. The voltage provided to the load **115** is substantially equal to the sum of the voltages across each of the capacitors **90**, **95**, **100** and **105**. The capacitors **90**, **95**, **100**, and **105** are preferably about 10,000 μF, but other capacitances are possible. While an LED is shown as the load **115**, other loads may be used.

[0028] While the charging circuit **50** is shown coupled to a single tree (i.e., the tree **110**), other configurations are possible. For example, each of the switches **55**, **65**, **75**, and **85** may be connected to separate trees. The switches **55**, **65**, **75**, and **85** could each be connected to multiple trees (or other non-animal organisms). One or more of the switches **55**, **65**, **75**, and **85** could each be connected to a single tree with multiple taps **107**. One of the switches **55**, **65**, **75**, and **85** could be connected to a single tree with a single tap, with the remainder of the switches **55**, **65**, **75**, and **85** being connected to multiple trees, each with multiple taps. One of the switches **55**, **65**, **75**, and **85** could be connected to a single tree with multiple taps, with the remainder of the switches **55**, **65**, **75**, and **85** being coupled to a single tree with multiple taps. Each of the switches **55**, **65**, **75**, and **85** may be coupled to a single tree or multiple trees using more than one of the tap **107**.

[0029] In operation, referring to FIG. **3**, with further reference to FIG. **2**, a process **260** for providing power derived from a tree to a load using the apparatus **40** includes the stages shown. The process **260**, however, is exemplary only and not limiting. The process **260** may be altered, e.g., by having stages added, removed, or rearranged.

[0030] At stage **264**, the charging circuit **50** is coupled to the living non-animal organism power source **110**, such as a tree, a plant, etc. Preferably, the tap **107** is inserted into the power source **110**. The tap **107** is inserted approximately 0.375 inches to 0.75 inches into the tree. Alternatively, a non-invasive tap may be used, e.g., a transformer core can be placed around a circumference of the tree.

[0031] At stage **268**, the charging circuit **50** is grounded. Preferably, the charging circuit **50** is coupled to a ground rod, or other suitable electrical ground, such as a ground connection in a typical residential power system. More current may be drawn from the living non-animal organism by the load **115** by increasing the depth that the ground rod is inserted into the ground and/or using multiple ground rods.

[0032] At stage **272**, the load **115** is coupled between the charging circuit **50** and the ground **120**. The load **115** is coupled on one side to the output **125** of the charging circuit **50** and on its other side to the ground **120**.

[0033] At stage **276**, the switches **55**, **60**, **65**, **70**, **75**, **80**, and **85** are actuated into the first (charging) state. The connections **56** and **61** of the switches **55** and **60** are closed, the connections **57** and **62** of the switches **55** and **60** are opened, and likewise for the switches **65**, **70**, **75**, **80**, and **85**. This couples the capacitors **90**, **95**, **100**, and **105** to the taps **107**.

[0034] At stage **280**, the power is provided from the tree **110** to the capacitors **90**, **95**, **100**, and **105**. The capacitors **90**, **95**, **100**, and **105** store energy received from the taps **107**.

[0035] At stage **284**, the capacitors **90**, **95**, **100**, and **105** are allowed to charge. The amount of time the capacitors **90**, **95**, **100**, and **105** are charged may vary to suit a specific application. For example, to provide sufficient power to illuminate the LED, each of the capacitors **90**, **95**, **100**, and **105** is charged to 0.5 Vdc. The amount of time for the capacitors **90**, **95**, **100**, and **105** to reach 0.5 Vdc may vary depending on the amount of power supplied by a particular power source.

[0036] At stage **288**, the switches **55**, **60**, **65**, **70**, **75**, **80**, and **85** are changed from the first state to the second state to discharge the power accumulated in the capacitors **90**, **95**, **100**, and **105**, thereby providing power to the load **115**.

[0037] The power from the capacitors **90**, **95**, **100**, and **105** is used to operate the load **115**, here causing the LED to emit light. The process **260** returns to stage **276** where the switches **55**, **60**, **65**, **70**, **75**, **80**, and **85** are changed from the second state to the first state, thereby providing power from the taps **107** to the capacitors **90**, **95**, **100**, and **105**.

[0038] Referring to FIGS. **2** and **4**, a filtered charging circuit **200** includes a filter circuit **205** and the charging circuit **50**, which are coupled to a power input **215**, a load **220** (in FIGS. **2** and **4** an LED), and a ground connector **250**. The filter circuit **205** is coupled between the power input **215** and the charging circuit **50**, and is configured to provide substantially DC power to the charging circuit **50**. The power input **215** is coupled to multiple taps **225** configured to be inserted into one or more trees. As described above with reference to FIG. **2**, the charging circuit can provide the load **220** with a stepped-up, substantially DC voltage.

[0039] The filter circuit **205** includes inductors **230** and **235**, and capacitors **240** and **245**. The inductors **230** and **235** are coupled in series between the power input **215** and the charging circuit **50** to inhibit high-frequency power produced by the tree from reaching the charging circuit **50**. The capacitor **240** is coupled between the junction of the inductors **230** and **235** and the ground **250**. The capacitor **245** is coupled between the junction of the inductor **235** and the charging circuit **50** and the ground **250**. For example, the inductors **230** and **235**, and the capacitors **240** and **245** are arranged in a 2-stage pie filter configuration. The capacitors short-out (e.g., ground) high-frequency power produced by the tree, further inhibiting non-DC power from being conducted to the charging circuit **50**. The inductors **230** and **235** are preferably about 10 mH, although other inductances are possible. The capacitors **240** and **245** are preferably about 470 μF, although other capacitances are possible. The charging circuit **50** is configured to receive substantially DC power from the filter circuit **205**, and to output intermittent DC power to the load **220** similar to the description provided above with respect to FIG. **2**.

[0040] In operation, referring to FIG. **5**, with further reference to FIG. **4**, a process **500** for providing power derived from a tree to the load **220** using the filtered charging circuit **200** includes the stages shown. The process **500**, however, is exemplary only and not limiting. The process **500** may be altered, e.g., by having stages added, removed, or rearranged.

[0041] At stage **505**, the filtered charging circuit **200** is coupled to the power input **215** such as a tree, a fungus, or other suitable non-animal organism, here by inserting the taps **225** into a single tree. Each of the taps **225** is inserted approximately 0.375 inches to approximately 0.75 inches into the tree. If any of the taps **225** are non-invasive, then that (those) taps(s) **225** (e.g., a transformer core) is (are) mounted accordingly. (e.g., placed around the circumference of a tree).

[0042] At stage **510**, the filtered charging circuit **200** is coupled to ground. The filtered charging circuit **200** is connected to the ground connector **250**, such as a rod, or other suitable electrical ground connector (e.g., a ground connection in a typical residential power system). More current may be drawn from the living non-animal organism by the load **220** by increasing the depth that the ground rod is inserted into the ground and/or using multiple ground rods.

[0043] At stage **515**, the switches **55**, **60**, **65**, **70**, **75**, **80**, and **85** are actuated into a first (charging) state coupling the capacitors **90**, **95**, **100**, and **105** to the filter circuit **205**. Power flows from the filter circuit **205** to the capacitors **90**, **95**, **100**, and **105**.

[0044] At stage **520**, the power derived from the tree is filtered to substantially remove alternating current (AC). At stage **520** the filter circuit **205** filters the power derived from the taps **225** into substantially DC power. The combination of the inductors **230** and **235** and the capacitors **240** and the **245** substantially filters out non-DC frequencies produced by the tree. The inductors **230** and **235** choke the high-frequencies produced by the tree. The capacitors **240** and **245** inhibit low frequency power and conduct high-frequency power to the ground connector **250**. The filter circuit **205** provides the filtered substantially DC power to the charging circuit **50**.

[0045] At stage **525** the filtered substantially DC power from the filter circuit **205** is provided to the capacitors **90**, **95**, **100**, and **105**. The switches **55**, **60**, **65**, **70**, **75**, **80**, and **85** are put in the first state to couple the circuit **205** to the capacitors **90**, **95**, **100**, and **105** to provide power to, and charge, the capacitors **90**, **95**, **100**, and **105**. At stage **530**, the capacitors **90**, **95**, **100**, and **105** are allowed to charge. The amount of time the capacitors **90**, **95**, **100**, and **105** are charged varies, and may be tailored to suit a specific application. For example, to provide sufficient power to illuminate the load **220**, each of the capacitors is charged to 0.5 Vdc. The amount of time required to reach 0.5 Vdc may vary depending on the amount of power supplied by a particular power source.

[0046] At stage **535**, the switches **55**, **60**, **65**, **70**, **75**, **80**, and **85** are changed from the first state to the second state to discharge the power accumulated in the capacitors **90**, **95**, **100**, and **105**, thereby providing power to the load **220**.

[0047] After stage **535**, the switches **55**, **60**, **65**, **70**, **75**, **80**, and **85** are actuated from the second state to the first state, thereby providing filtered substantially DC power from the filter circuit **205** to the charging circuit **50**. The stages **515**, **520**, **525**, and **530** may be repeated.

[0048] At stage **540**, the power from the capacitors **90**, **95**, **100**, and **105** is used to operate the load **220**, here causing the LED to emit light. The process **500** returns to stage **515** where the switches **55**, **60**, **65**, **70**, **75**, and **85** are changed from the second state to the first state, thereby providing power from the taps **225** to the capacitors **90**, **95**, **100**, and **105**

[0049] Referring to FIG. **6**, a filtered charging circuit **300** includes a filter circuit **305** and a charging circuit **310**, which are coupled to a power input **315** and a load **320** (in FIG. **6**, an LED). The filter **305** is coupled between the power input **315** and the charging circuit **310**, and is configured to provide substantially DC power to the charging circuit **310**. The power input **315** is coupled to multiple taps **325** that are each configured to be inserted into a tree. The load **320** is preferably a SSL-DSP5093UWC LED (manufactured by Lumex Incorporated, of Palatine, Ill.), although other LEDs, and other types of loads, may be used.

[0050] The filter circuit **305** includes inductors **330** and **335**, capacitors **340** and **345**, and an output node **347**. The inductors **330** and **335** are coupled in series between the power input **315** and the output node **347** and are of inductances to serve as chokes of any high-frequencies received at the power input **315**. The capacitor **340** is coupled between the junction of the inductors **330** and **335** and the ground **348**. The capacitor **345** is coupled between the output node **347** and the ground **348**. For example, the inductors **330** and **335**, and the capacitors **340** and **345** are arranged in a 2-stage pie filter configuration. The inductors **330** and **335** are preferably about 10 mH, although other inductances are possible. The capacitors **340** and **345** work in conjunction with the inductors **330** and **335** shorting-out high frequency signals that may have passed through the inductors **330** and **335**, respectively. The capacitors **340** and **345** are preferably about 470° F., although other capacitances are possible.

[0051] The charging circuit **310** includes capacitors **350**, **355**, **360**, and **365**, diodes **370**, **375**, and **380**, a switch **385**, a battery **390**, and a ground connection **349** connected to the ground **348**. Coupled between the output node **347** and the ground connection **349** are the capacitors **350**, **355**, **360**, and **365**, and the diodes **370**, **375**, and **380**, in an alternating series of capacitors and diodes. Anodes **371**, **376**, and **381** of the diodes **370**, **375**, and **380**, respectively, are coupled to the output node **347**. Cathodes **372**, **377**, and **382** of the diodes **370**, **375**, and **380**, respectively, are coupled to the ground connection **349**. The capacitor **350** is coupled between the cathode **372** of the diode **370** and the output node **347**. The capacitor **365** is coupled between the anode **381** of the diode **380** and the ground connection **349**. The capacitors **350**, **355**, **360**, and **365**, and the diodes **370**, **375**, and **380** act as a voltage multiplier circuit to allow filtered substantially DC power to charge the capacitors **350**, **355**, **360**, and **365** (e.g., by summing the voltages across the capacitors **350**, **355**, **360**, and **365**). Using the capacitors **350**, **355**, **360**, and **365**, and the diodes **370**, **375**, and **380**, a higher voltage (e.g., 2-2.5 V) is produced to charge the battery **390**. The capacitors **350**, **355**, **360**, and **365** are 5,000 μF, although other capacitances are possible, such as 10,000 μF. The diodes **370**, **375**, and **380** are preferably 1N5417 diodes, but other diodes are possible.

[0052] The battery **390** is coupled between the output node **347** and the ground **348** such that it may receive power from the output node **347**. The battery **390** is preferably a lithium-ion battery, but other batteries may be used. A positive terminal **391** of the battery **390** is coupled to the output node **347** and the switch **385**. A negative terminal **392** of the battery **390** is coupled to the ground **348**. Other configurations are possible (e.g., coupling the negative terminal **392** to the output node **347**, and coupling the positive terminal **391** to the ground **348**).

[0053] The switch **385** is coupled between a terminal **322** of the load **320** and output node **347** to control a power flow to the load **320**. When the switch **385** is in an open state (as shown), power is inhibited (and preferably prevented) from flowing to the load **320**. When the switch **385** is in a closed state, power may flow to the load **320**. A terminal **321** of the load **320** is coupled to the ground **348**.

[0054] In operation, referring to FIG. **7**, with further reference to FIG. **6**, a process **600** for providing power derived from a tree to the load **320** using the filtered charging circuit **300** includes the stages shown. The process **600**, however, is exemplary only and not limiting. The process **600** may be altered, e.g., by having stages added, removed, or rearranged.

[0055] At stage **605**, the filtered charging circuit **300** is coupled to the power input **315** such as a tree, a fungus, or other suitable non-animal organism, here by inserting the taps **325** into a single tree. Each of the taps **325** is inserted approximately 0.375 inches to approximately 0.75 inches into the tree. If any of the taps **325** are non-invasive, then that (those) taps(s) **325** (e.g., a transformer core) is (are) mounted accordingly. (e.g., placed around the circumference of a tree).

[0056] At stage **610**, the filtered charging circuit **300** is coupled to ground. The filtered charging circuit **300** is connected to the ground connector **349**, such as a rod, or other suitable electrical ground connector (e.g., a ground connection in a typical residential power system). More current may be drawn from the living non-animal organism by the load **320** by increasing the depth that the ground rod is inserted into the ground.

[0057] At stage **615**, the switch **385** is actuated into the first state (i.e., open) where the load **320** is disconnected from the filtered charging circuit **300** and current is inhibited/prevented from reaching/operating the LED **320**.

[0058] At stage **620**, the power derived from the tree is filtered to substantially remove alternating current (AC). At stage **620** the filter circuit **305** filters the power derived from the taps **325** into substantially DC power. The combination of the inductors **330** and **335** and the capacitors **340** and the **345** substantially filters out non-zero frequencies produced by the tree. The inductors **330** and **335** choke the high-frequencies produced by the tree. The capacitors **340** and **345** inhibit low frequency power and conduct high-frequency power to the ground connector **349**. The filter circuit **305** provides the filtered substantially DC power to the charging circuit **310**.

[0059] At stage **625**, the filtered substantially DC power is provided to the charging circuit **310** via the output node **347**. Power provided from the output node **347** is conducted through the capacitors **350**, **355**, **360**, and **365**, and the diodes **370**, **375**, and **380**. The configuration of the diodes **370**, **375**, and **380** allows substantially only filtered DC power to charge the capacitors **350**, **355**, **360**, and **365**.

[0060] At stage **630**, the battery **390** is charged using power from the output node **347** and the capacitors **350**, **355**, **360**, and **365**. The amount of time the battery **390** is charged varies, and may be tailored to suit a specific application. The battery **390** may be charged for a specific predetermined amount of time, or may be charged until a certain power threshold is reached.

[0061] At stage **635** the switch **385** is actuated into the second state (e.g., closed) coupling the load **320** across the terminals **391** and **392** of the battery **392**, thereby providing power from the battery **390** to the LED **320**. Power may also be provided to the load **320** from the output node **347** and/or the capacitors **350**, **355**, **360**, and **365**. The stages **615**, **620**, **625**, **630**, and **635** may be repeated.

[0062] At stage **640**, the power from the capacitors **350**, **355**, **360**, and **365**, and the battery **390** is used to operate the load **320**, here causing the LED to emit light. The process **600** returns to stage **615** where the switch **385** is changed from the second state to the first state, thereby decoupling the load **320** from the positive terminal **391** of the battery **390**, the output node **347**, and the capacitor **350**. The switch **385** thus alternates between the first state and the second state to provide intermittent power to the LED **320**. Alternatively, the switch **385** can remain in the second state to provide substantially constant power to the LED **320**. Other modes of operation are also possible.

[0063] In operation, referring to FIG. **8**, with further reference to FIG. **1**, a process **1000** for determining storm distance and/or severity by measuring the voltage provided by the tree **25** includes the stages shown. The process **1000**, however, is exemplary only and not limiting. The process **1000** may be altered, e.g., by having stages added, removed, or rearranged.

[0064] At stage **1005**, the voltage provided by the tree **25** is measured using the apparatus **1**. Voltage values are recorded, e.g., at regular time intervals such as every 30 seconds, although other intervals are possible. Preferably, the apparatus **1** is not used to provide power to a load (e.g., the load **35**) during stage **1005**, although the apparatus **1** can provide power to a load simultaneously with the voltage measurements. The voltage can be measured, for example, by a computer and/or manually.

[0065] At stage **1010**, the voltage measurements are tracked. For example, a computer system can collect the voltage readings at regular intervals and store the values in a data table with each entry in the table representing a discrete voltage measurement at a known time. Alternatively, a person taking manual measurements can record the measurements manually.

[0066] At stage **1015**, the voltage measurements are compared to a baseline voltage for the tree **25** (e.g., a voltage value collected on a clear day). If the voltage measurements decrease relative to the baseline voltage of the tree **25**, then a conclusion can be reached and an indication can be provided that a storm (e.g., a lightning storm) is approaching. The amount of the voltage drop and/or the speed of the voltage drop when compared to the baseline voltage can be used to determine the severity and/or the distance of an approaching storm. For example, a 0.5V drop in twenty minutes (with the baseline voltage as a reference point) can result in a determination that a more severe storm is approaching than a 0.2V drop in an hour (with the baseline voltage as a reference point). The voltage readings collected and tracked at stages **1005** and **1010** can be used at stage **1015** to determine information about an approaching storm alone (e.g., distance and/or severity), or can be combined with other weather tools, such as Radar and/or satellite imagery, used in predicting weather conditions.

Experiment 1

[0067] Referring to Appendix A, exemplary results of voltage yield tests from different trees using different tap configurations, different ground rod quantities, and different numbers of taps are shown. The tests were performed using the configuration shown in FIG. **1**, and described in the corresponding written description, where the load was a voltmeter. The circuit **30**, however, as shown in FIG. **1**, was omitted in the tests. The tests were performed selecting different geographic locations of the trees, different types of trees, different tap materials, different tap depths, different tap diameters, different tap heights (i.e., height from ground level), different tree altitudes, varying numbers of taps, and varying soil conditions. As shown in Appendix A, factors such as the species and/or the variety of a particular plant, e.g., tree, affects the available voltage and/or current. For example, an oak tree located 40 feet above sea level and a maple tree located 200 feet above sea level provided differing amounts of voltage and/or current. Trees produced a substantially constant DC voltage (and some AC voltage), while other plants produced a less-constant DC voltage than trees. Furthermore, two trees, providing about 0.75V and 0.8V (DC), respectively, were coupled in series. Approximately 0.8V was measured from the second of the two tree coupled in series.

Experiment 2

[0068] The charging circuit **50** (of FIG. **2**) was used to successfully power an LED. The charging circuit **50**, using four 10,000 μF (35 Vdc) capacitors, successfully illuminated an SSL-DSP5093UWC LED (manufactured by Lumex Incorporated, of Palatine, Ill.) for approximately one second. The charging circuit **50** was placed in the charging state for approximately 1.75 hours, thereby charging the capacitors **90**, **95**, **100**, and **105**. At the end of the charging period, there was approximately a 0.5 Vdc potential in each of the capacitors **90**, **95**, **100**, and **105**, storing approximately 0.0125 Joules of energy in each of the capacitors **90**, **95**, **100**, and **105**. To light the LED, the switches **55**, **60**, **65**, **70**, **75**, **80**, and **85** were actuated, changing the switches **55**, **60**, **65**, **70**, **75**, **80**, and **85** from the first (charging) state, to the second (discharge) state, thereby providing 2 Vdc to the LED (4×0.5 Vdc) and illuminating the LED. After approximately one second of the LED being illuminated, the voltage across the LED dropped to 1.5 Vdc and the LED no longer illuminated (the lower operating threshold of the SSL-DSP5093UWC LED is approximately 1.5V). The capacitors **90**, **95**, **100**, and **105** were allowed to recharge for approximately one hour to again reach a 0.5 Vdc potential across each of the capacitors **90**, **95**, **100**, and **105**.

Experiment 3

[0069] The apparatus was used to collect weather related information (exemplary data is shown in Appendix B). Voltage readings were collected as a lightning storm approached from the West of a test site including a tree. As the storm approached the test site, a voltage provided by the tree decreased relative to prior levels. The closer the storm was relative to the test site, the larger the voltage drop. For example, when the storm was several miles away, the voltage provided by the tree dropped about 0.2V compared to a voltage measured from the tree on a clear day. As the storm had substantially reached the test site, the voltage provided by the tree had dropped approximately 0.5V compared to the voltage measured from the tree on a clear day. The approaching storm was an intense lightning storm, including positive lightning. Data consistent with the above description was recorded during other lightning storms. Observations indicate that stronger electrical activity (e.g., lightning) produced by a storm caused a quicker and larger voltage drop. Thus, by measuring the voltage provided by the tree **25**, it was possible to gather information regarding the severity of an approaching storm. After a storm had passed over the test site, the voltage provided by the tree would return to "normal" levels within about thirty-five to forty minutes.

Experiment 4

[0070] A modified version of the apparatus **1** shown in FIG. **1** was used to stimulate/enhance the growth of plants including tomato and broccoli plants. Providing electricity produced by a tree to a plant was found to increase growth of the plant, to increase the plant's resistance to pests, and to increase the plant's resistance to frost. A tree was coupled to a plant using the tap **5** and the wire **15**, with the plant being the load **35**. The plant's root system replaced the conductor **10**.

Broccoli Plant

[0071] One of several broccoli plants in a group near each other was coupled to an apple tree as described above during an entire growing season. Prior to coupling the apple tree to the broccoli plant, the apple tree produced about 1.1 Vdc and the broccoli plant produced an average of about 0.3 Vdc. As the growing season progressed, the "energized" broccoli plant showed increased growth and increased resistance to pests relative to the other neighboring broccoli plants. For example, the energized broccoli plant grew taller than the other neighboring broccoli plants, and produced a larger center head and more side heads than the other neighboring broccoli plants. An additional experiment was performed by energizing the smallest and weakest broccoli plant of the group of broccoli plants. Within about two to three days of being energized, the newly-energized broccoli plant was about the same size and height as the neighboring non-energized broccoli plants.

[0072] The energized broccoli plant was not bothered by pests, whereas the non-energized broccoli plants were attacked by pests. As determined by several visual inspections during the growing season, the energized broccoli plant was substantially untouched by pests, whereas the non-energized broccoli plants' leaves were eaten by pests. As a further experiment, a worm was placed on the energized broccoli plant and then onto one of the other broccoli plants. After being placed on the "energized" broccoli plant, the worm did not eat the broccoli plant and fell off. When the same worm was placed on the non-energized broccoli plant, the worm began eating the broccoli plant soon thereafter. An additional experiment was performed by energizing a pest-inhabited broccoli plant. Within about one hour of being energized, the pests inhabiting the broccoli plant vacated the plant.

Tomato Plant

[0073] One of several Cherokee Purple tomato plants in a group near each other was coupled to an elm tree. Prior to coupling the elm tree to the tomato plant, the elm tree produced about 1.2 Vdc. The energized/connected tomato plant included four shoots, each of which were coupled to the elm tree. Visual inspections of the tomato plant revealed that the energized tomato plant grew approximately thirty-three percent higher than the non-energized plants. The energized tomato plant also produced more tomatoes than the non-energized tomato plants. Furthermore, the energized tomato plant survived the first two frosts of the winter season, whereas the non-energized tomato plants died after the first frost.

[0074] Other embodiments are within the scope and spirit of the invention, including the appended claims. Features implementing functions may be physically located at various positions, including being distributed such that portions of functions are implemented at different physical locations. Loads other than LEDs may be used, such as a transmitter, receiver, microchip, incandescent light source, infrared light source, a laser, a DC/DC voltage converter, a DC/AC inverter, etc. Power may be drawn from non-animal organisms other than trees. For example, broccoli plants, tomato plants, soybean plants, and mushrooms may be used. Also, potted plants, and potted trees may be used. The tap may be inserted into a branch of the tree. The load can draw more current from the tree using multiple ground rods.

[0075] While the tap has been disclosed as a nail, other configurations are possible such as a staple. Non-invasive embodiments of the tap are possible, e.g., a donut-shaped transformer core placed around the circumference of a tree. The surface area of a tap may be increased by, for example, being threaded (e.g., being a screw) and/or placing outwardly disposed barbs on the tap. A tap may have a flange disposed around the circumference of the tap to help a user insert the tap correctly into a tree (e.g., to the correct depth). A tap may include a handle to help in insertion into the tree and/or removal from the tree.

[0076] While the terms "connected," "connector," "coupled," and "connection" have been used to indicate a direct connection, other configurations are possible. For example, referring to FIG. **6**, when the diode **380** is "coupled" to the capacitor **360**, this may include indirect connection through another component (e.g., a resistor coupled between the cathode **382** of the diode **380** and the capacitor **360**).

[0077] The word "or" is to be construed as including the conjunctive and disjunctive definition.

[0078] Further, while the description refers to the invention, the description may include more than one invention.

Roofing Nail	Potted Tree	Copper	Earth	0.00	0.00	0.00	Held waist high

[0079] The potted tree was a Norfolk Island Pine approximately three feet tall, which was potted in a plastic pot about 40 mils. thick.

APPENDIX B

Test 1:

Time	Storm distance	DC Voltage from tree
Baseline Voltage	—	1.2 V
11:00 AM	About 100 miles	1.1 V
12:00 PM	About 50-60 miles	1.0 V
		0.5 V
		1.0 V
		0.5 V
2:00 PM	Dissipated	1.2 V

[0080] The 12:00 PM measurements reflect fluctuations when lightning strikes occurred.

Test 2:

Time	Storm distance	DC Voltage from tree
Baseline Voltage	—	1.2 V
3:00 PM	50-60 miles	1.1 V
3:15 PM	40-50 miles	1.0 V
		0.3 V
		1.0 V
		0.3 V
3:30 PM	Dissipated	1.2 V

[0081] The 3:15 PM measurements reflect fluctuations when lightning strikes occurred.

Test 3:

Time	Storm distance	DC Voltage from tree
Baseline Voltage	—	1.1 V
7:45 PM	50-60 miles	1.1 V
7:55 PM	40-50 miles	0.72 V
		0.85 V
		0.72 V
9:16 PM	Dissipated	1.1 V

[0082] The 7:55 PM measurements reflect fluctuations when lightning strikes occurred.

What is claimed is:

1. A method for drawing electricity from a non-animal organism, the method comprising:

coupling a first electrical conductor to the non-animal organism;

coupling a second electrical conductor to a ground rod;

embedding the ground rod into soil at a predetermined depth as a function of a desired current level, whereby the current available from the non-animal organism is increased by increasing the depth that the ground rod is embedded into the soil;

coupling an electrical load between the first electrical conductor and the second electrical conductor, the electrical load being configured to draw electricity from the non-animal organism via the first electrical conductor; and

operating the electrical load using electricity drawn from the non-animal organism.

2. A system comprising:

a non-animal organism;

a first electrical conductor electrically coupled to the non-animal organism;

a plurality of ground rods embedded into soil wherein a quantity of the plurality of ground rods is a function of a desired current level from the non-animal organism, whereby the current available from the non-animal organism is increased by increasing the quantity of the plurality of ground rods;

a second electrical conductor coupled to the plurality of ground rods; and

an electrical load coupled between the first electrical conductor and the second electrical conductor to draw electricity from the non-animal organism, the electrical load using electricity drawn from the non-animal organism.

3. A method of predicting weather using electricity from a non-animal organism, the method comprising:

coupling a first electrical conductor to the non-animal organism;

coupling a second electrical conductor to a ground;

coupling a voltmeter between the first electrical conductor and the second electrical conductor;

measuring a voltage potential between the first and second electrical connectors;

providing a weather prediction as a function of the measured voltage potential.

4. The method of predicting weather of claim **3** further comprising:

determining a baseline voltage reading for the non-animal organism under a first weather condition;

determining a plurality of voltage readings over time;

comparing each of the plurality of voltage readings to the baseline voltage reading to determine differences between the baseline voltage reading and each of the plurality of voltage readings; and

calculating information indicative of a second, future weather condition as a function of the differences.

5. A system for use with live vegetative matter growing in soil, the system comprising:

a non-animal organism;

a first electrical conductor electrically coupled to the non-animal organism; and

a second electrical conductor coupled to the first electrical conductor and coupled to the live vegetative matter, the second electrical conductor providing electricity from the non-animal organism to the live vegetative matter;

wherein the growth of the live vegetative matter is stimulated by the electricity provided by the non-animal organism.

6. A system comprising:

a non-animal organism;

a first electrical conductor electrically coupled to the non-animal organism;

a second electrical conductor coupled to a ground; and

an electrical load coupled between the first electrical conductor and the second electrical conductor to draw electricity from the non-animal organism, the electrical load using electricity drawn from the non-animal organism;

wherein the load is selected from the group consisting of:

a battery;
a battery charging circuit;
a sensor;
a radio frequency identification chip;
a transmitter;
a receiver;
a global positioning service (GPS) device;
a light emitting device; and
a fire ignition system.

7. The system of claim **6** wherein the load is the sensor and the sensor is selected from the group consisting of:

an oxygen sensor;
an air-speed sensor;
a humidity sensor;
a barometric pressure sensor;
a camera;
a photoelectric sensor;
a altitude sensor;
a smoke detector;
a microphone; and
a vibration sensor.

8. The system of claim **6** wherein the load is the GPS device and the GPS device is selected from the group consisting of:

a GPS receiver;
a GPS transmitter;
a GPS guidance system; and
a GPS navigation system.

9. The system of claim **6** wherein the load is the light emitting device and the light emitting device is selected from the group consisting of:

a light emitting diode configured to emit visible light; and

an infrared light emitting diode configured to emit an infrared signal.

(57) **ABSTRACT**

A rectenna capable of power conversion from electromagnetic (EM) waves of high frequencies is provided. In one embodiment, a rectenna element generates currents from two sources—based upon the power of the incident EM wave and from an n-type semiconductor, or another electron source attached to a maximum voltage point of an antenna element. The combined current from both sources increases the power output of the antenna, thereby increasing the detection sensitivity of the antenna of a low power signal. Full wave rectification is achieved using a novel diode connected to a gap in the antenna element of a rectenna element. The diode is conductive at forward bias voltage or reverse bias voltage, and rectifies the antenna signal generated by the desired EM wave received by antenna raise from The rectenna element of the present invention may be used as a building block to create large rectenna arrays.

EM RECTIFYING ANTENNA SUITABLE FOR USE IN CONJUNCTION WITH A NATURAL BREAKDOWN DEVICE

CROSS REFERENCE TO RELATED APPLICATIONS

[0001] The present application is a continuation-in-part application of, and claims priority to, co-pending U.S. patent application ("Co-pending Patent Application"), Ser. No. 10/963,357, entitled "EM Rectifying Antenna Suitable for use in Conjunction with a Natural Breakdown Device," filed on Oct. 12, 2004, bearing Attorney Docket No. M-15617 US. The Co-pending patent application is hereby incorporated by reference in its entirety.

BACKGROUND OF THE INVENTION

[0002] 1. Field of the Invention

[0003] The present invention relates to an energy conversion device using rectifying antennae ("rectannae"). In particular, the present invention relates to an energy conversion device which converts electromagnetic wave energy to electrical energy using a semiconductor device that rectifies a small high frequency signal.

[0004] 2. Discussion of the Related Art

[0005] FIG. **1** shows the current versus voltage characteristics of a conventional pn junction diode. FIG. **2** is a schematic representation of conventional abrupt pn junction diode **100**. As shown in FIG. **2**, conventional pn junction diode **100** includes p-region **101** and n-region **102**. P-region **101** may be doped, for example, using a p-type dopant (i.e., electron acceptor, such as boron) and n-region **102** may be doped using an n-type dopant (i.e., an electron donor, such as phosphorus). Near the abrupt junction between p-region **101** and n-region **102**, equilibrium due to the difference in electrochemical potentials of the two regions and the diffusion of charge carriers (e.g., electrons and "holes") between the two regions deplete the charge carriers to form "depletion regions" **103** and **104** in p-region **101** and n-region **102**, respectively. Under a so-called "abrupt junction approximation", the widths x_p of depletion region **103** and x_n for depletion region **104**, with an externally imposed voltage V across the pn junction, are given, respectively by:

$$x_n = \sqrt{\frac{2\varepsilon_s N_A(\phi_i - V)}{qN_D(N_A + N_D)}}$$

$$x_p = \sqrt{\frac{2\varepsilon_s N_D(\phi_i - V)}{qN_A(N_A + N_D)}}$$

where ϵ_s is the electrical permittivity of silicon, q is the charge of an electron, ϕ_i is the "built-in" potential of the pn junction, N_A and N_B are the doping concentrations of p-region **101** and n-region **102**, respectively.

[0006] As shown in FIG. **1**, the horizontal axis shows the voltage V across the pn junction, and the vertical axis shows the diode current I_D across the pn junction. As shown in FIG. **1**, when voltage V across the pn junction is greater than zero volts and greater than voltage V_{th} (the "threshold voltage"), the pn junction is strongly "forward biased" and the diode current I_D grows exponentially with the voltage V. When the voltage V across the pn junction is less than 0 volts, but not less than the voltage V_{br} (the "breakdown voltage"), the pn junction is "reverse biased" and the diode current I_D is very small. Under reversed bias, as the voltage grows in magnitude, the carriers generated increases in energy, leading to phenomena such as tunneling and impact ionization at voltage V_{br}. At voltage V_{br}, the diode current I_D becomes very large and the diode has "broken down." At breakdown, the magnitude of the average electrical field (in volts per centimeter) across the pn junction is given by the empirical expression:

$$|E_{br}| = \frac{4.0 \times 10^5}{1 - \frac{1}{3}\log\frac{N_D}{10^{16}}}$$

where N_D is the lesser of N_A and N_B.

SUMMARY

[0007] The present invention provides a rectifying antenna ("rectenna") capable of converting power from high frequency electromagnetic (EM) waves in free space to electrical energy. According to one embodiment of the present invention, an antenna generates currents from two sources—from a potential difference generated by an incident EM wave in the antenna, and from an n-type semiconductor or another electron source attached to a maximum voltage point of an antenna. The combined current from both sources increases the power output of the antenna, thereby increasing the detection sensitivity of the antenna of a low power signal.

[0008] According to one embodiment of the present invention, full wave rectification is achieved using a novel diode connected to an antenna. In that embodiment, the diode is conductive at a reverse bias voltage, stores charge at forward bias, and rectifies the antenna signal generated by the targeted electromagnetic (EM) radiation within a selected spectrum received by antenna. The diode and the antenna form a rectenna. In one embodiment of the present invention, half wave rectification is achieved using the diode.

[0009] The rectenna of the present invention may be used as a building block to create large rectenna arrays. Thus, microwave, sub-millimeter wave, THz wave, IR wave and visible wave applications may be found in a rectenna of this invention. A rectenna of the present invention is scalable, so that future improvements are possible with improvements of semiconductor technology, material science, device physics and antenna design. There is also no upper limit to the frequencies that can be received using such a rectenna. The present invention is applicable to EM-to-DC power generation and supply, heat shield, humidity, food production, dermatology (e.g., examination of burned skin structure without biopsy) and tomography (and other medical imaging sensing). The present invention allows T-rays replacement of Roentgen rays (X-rays) in imaging of objects, such as those used to inspect pallets in certain airport safety procedures or in drug detection procedures. The present invention is also applicable to chemical analysis using flames and gases (e.g., toxicity analysis, Fourier spectrum), quality control procedures (e.g., detection of holes in plastic parts, such as those used in automobile applications), and radar applications (e.g., measurement of reflection)

[0010] According to another aspect of the present invention, a "natural breakdown device" ("NBD") allows current to flow even with a zero bias voltage. NBD is a natural breakdown device of the diode type, according to one embodiment of natural breakdown invention. An NBD may be used as a rectifier on the rectenna of the present invention to rectify small amplitude high frequency electromagnetic signals.

[0011] The present invention is better understood upon consideration of the detailed description below and the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

[0012] FIG. **1** shows the current (I) versus voltage (V) characteristics of a conventional pn junction diode.

[0013] FIG. **2** is a schematic representation of conventional pn junction diode **100**.

[0014] FIG. **3** is a schematic representation of a natural breakdown device (NBD) **300**, according to one embodiment of the present invention.

[0015] FIG. **4** shows the relationship between the built-in voltage V_{FD} and bias voltage V_{IN} across NBD **300** during operation.

[0016] FIG. **5** shows the current-voltage (IV) characteristics of NBD **300** when the value of voltage V_s is not close to the threshold voltage V_{th} of NBD **300**.

[0017] FIG. **6**(*a*) is a schematic representation of a natural breakdown device (NBD) **600**, having an N-type region that is fully depleted at zero bias voltage, according to one embodiment of the present invention.

[0018] FIG. **6**(*b*) shows an NBD **600** that has both p-type and n-type regions fully depleted at zero bias voltage, according to one embodiment of the present invention.

[0019] FIGS. **7**(*a*) to **7**(*c*) show NBD **700**, NBD **710** and NBD **720**, each including a depleted region (e.g., depletion regions **701**, **711**, **721** or **722**), at zero applied voltage bias.

[0020] FIGS. **8**(*a*) to **8**(*f*) show NBD **800**, NBD **810** and NBD **820** each including a forced depletion region (e.g., depletion region **801**, **811**, **821** and **822**) having two or more doping concentrations at zero applied voltage bias. In particular, FIG. **8**(*f*) shows multiple NBD **600**s connected in series at zero bias.

[0021] FIG. **9** shows rectenna array **900** including numerous antennae (e.g., antenna **904**, **914** and **924**) constructed in accordance with one embodiment of the present invention.

[0022] FIGS. **10**(*a*) and **10**(*b*) show top and side views of one embodiment of the invention, illustrating gap dipole antenna **904** in rectenna array **900** of FIG. **9**, in accordance with one embodiment of the present invention.

[0023] FIG. **11** shows gap rectenna arrays **1101** and **1102** connected in series for DC power collection, showing electron output channel **1104** of rectenna array **1101** being connected to electron input channel **1105** of rectenna array **1102**.

[0024] FIGS. **12**(*a*) and **12**(*b*) show, respectively, the top and side views of gapless dipole antenna **1200**, in accordance with one embodiment of the present invention.

[0025] FIG. **13** shows rectenna array **1300** including numerous gapless antennae.

[0026] FIG. **14** shows rectenna arrays **1401** and **1402** connected in series for DC power collection, showing electron output channel **1404** of rectenna array **1402** being connected to electron input channel **1403** of rectenna array **1401**.

[0027] FIG. **15**(*a*) to **15**(*d*) shows schematic representations of various NBDs at zero applied voltage bias, according to one embodiment of the present invention.

[0028] FIG. **16**(*a*) to **16**(*b*) shows, schematic representations of various configurations of NBDs at zero applied bias voltages, according to one embodiment of the present invention.

[0029] FIGS. **17**(*a*) to **17**(*f*) show schematic representations of various NBDs at zero applied voltages, according to one embodiment of the present invention.

[0030] FIG. **18**(*a*) is a schematic representation of NBD **1800** at zero applied bias voltage, according to one embodiment of the present invention; NBD **1800** represents a natural breakdown Schottky diode under a forced depletion condition.

[0031] FIG. **18**(*b*) is a schematic representation of NBD **1810** at zero applied bias voltage, according to one embodiment of the present invention; NBD **1810** represents a natural breakdown Schottky diode under a forced depletion condition.

[0032] FIG. **19**(*a*) is a schematic representation of NBD **2000** at zero applied bias voltage, according to one embodiment of the present invention; NBD **2000** represents an NPN bipolar transistor with one region under a forced depletion condition.

[0033] FIG. **19**(*b*) is a schematic representation of NBD **2010** at zero applied voltage bias, according to one embodiment of the present invention; NBD **2010** represents a natural breakdown NPN bipolar transistor having two regions under a forced depletion conditions.

[0034] FIG. **19**(*c*) is a schematic representation of NBD **2020** at zero applied voltage bias, according to one embodiment of the present invention; NBD **2020** represents a natural breakdown NPN device with one region fully depleted.

[0035] FIGS. **20**(*a*) and **20**(*b*) show, respectively, the top and side views of gapless dipole rectenna element **2200**, in accordance with one embodiment of the present invention.

[0036] FIG. **21** shows, gap rectenna arrays **2300** and **2350** connected in parallel, according to one embodiment of present invention.

[0037] FIGS. **22**(*a*) and **22**(*b*) show rectifier structure **905***a* provided for signal rectification, according to one embodiment of the present invention.

[0038] FIG. **23** shows the current-voltage (IV) characteristics of NBD **300** when contact resistance is very low.

[0039] FIG. **24** shows the current-voltage (IV) characteristics of NBD **300** when voltage V_s is close to threshold voltage V_{th}.

[0040] FIG. **25**(*a*) shows the current-voltage (IV) characteristics of NBD **300** utilizing degenerate material when the value of V_s is not close to threshold voltage V_{th}.

[0041] FIG. **25**(*b*) shows the current-voltage (IV) characteristics of NBD **300** utilizing degenerate material when the voltage V_s is close to threshold voltage V_{th}.

[0042] FIG. **26** shows the current-voltage (IV) characteristics of NBD **2000**.

[0043] FIGS. **27.1** to **27.2** are tables of various NBD structures with their corresponding characteristics.

[0044] FIG. **28** shows the current-voltage (IV) characteristics of NBD **2020**.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

[0045] While the following description discloses mainly dipole rectangular antenna ("rectenna") elements in square array configurations (i.e., two-dimensional antenna arrays each having the same number of antenna elements along each dimension), the present invention is applicable to rectennae of other configurations, such as a two-dimensional configuration having different number of antenna elements along the two dimensions. The present invention provides an array of dipole rectennae elements configured to capture and harvest electromagnetic energy for power generation.

[0046] One embodiment of the present invention is shown in FIG. **9**. FIG. **9** shows rectenna array **900** including numerous antennae (e.g., antennae **904**, **914** and **924**). FIGS. **10**(*a*) and **10**(*b*) are top and side of rectenna array **900** of FIG. **9**, showing dipole antenna **904**, which includes antenna sections **904***a* and **904***b* contacting rectifier structure **905***a*. Rectifier structure **905***a* rectifies the signal received at antenna **904***a* and **904***b*. Rectifier structure **905***a* may be provided, according to this embodiment of the present invention, by a "natural breakdown device" (NBD), which is further discussed below in this detailed description and referred to as a "Natural Breakdown Device" (NBD) or), a natural breakdown PN junction diode.

[0047] As shown in FIGS. **10**(*a*) and **10**(*b*), rectifier structure **905***a* includes an NBD which includes p-region **906** and n-region **907**. P-region **906** has a width that is fully depleted at a zero bias voltage condition. In this description, when a depletion region has a width that is smaller than the width of the depletion at zero applied voltage bias at an abrupt junction for the same doping concentrations, that depletion region is said to be "forced". The forced depleted p-region **906** of rectifier structure **905***a* connects directly to the antenna. The n-region **907** of rectifier structure **905***a* connects directly to an output channel **909**. Rectifier structure **905***a* may also be provided by two NBDs, according to one embodiment of the present invention, as shown in FIGS. **22**(*a*) and **22**(*b*). Using two NBDs, each connected to a different one of the antenna sections **904***a* and **904***b*, shorting of the antenna sections by the NBD may be avoided.

[0048] Some rectifier qualities of rectifier structure, such as **905***a*, which allow dipole antenna **904** and other antennae presented in the present invention operate efficiently include: (1) being conducting near zero reverse bias voltage or near zero forward bias voltage. (2) having a current that is significantly greater than a leakage current of a conventional pn-junction diode in reverse bias, (3) rectifying input signal by producing a current in a predetermined direction, and (4) when the rectifier structure is connected with an voltage source, the input voltage is raised.

[0049] As shown in FIG. **10**(*b*), each dipole antenna **904** has a length L and is made up from two antenna sections (e.g., sections **904***a* and **904***b*) separated in the center of the antenna by a gap of length D. Length L is ideally one-half the wavelength of the electromagnetic (EM) wave that antenna is designed to receive, D is typically significantly smaller than the smallest wavelength of the electromagnetic (EM) wave the antenna is expected to receive. P-region **906** of rectifier structure **905***a* (NBD **300**) is connected, on one side, next to the gap of antenna **904**, to both sections **904***a* and **904***b* and, on the other side, to n-region **907**. Heavily doped n+-regions **908** connect to both ends of antenna **904**. A rectenna element is thus formed by antenna **904**, rectifier structure **905***a*, and n+-regions **908**. N+-regions **908** of multiple rectenna elements are connected to constitute input channel **902** for electrons. Similarly, heavily doped n+-regions **909** connect the n-regions of multiple rectifier structures (e.g., n-region **907** of rectifier structure **905***a*) in parallel to form output channel **903** for electrons. Antenna sections of each antenna are isolated from the antenna sections of other antennae, so that each antenna may attain whatever voltage level due to the EM wave incident to that antenna. N+ regions **908** and electron input channel **902** have the same conductivity type. In another embodiment, n+-regions **908** and **902** may be replaced by heavily doped p+-regions.

[0050] When an EM wave of wavelength **2**L is received by the dipole antenna, a voltage difference is created between the ends of the antenna sections. Relative to the anode portion of the rectifier structure at the center of the dipole antenna, the voltages at the opposite ends of the dipole antennae are at opposite polarities. The resistances between n+-regions **908** to antenna **904** and between antenna **904** and the NBD are very small. The voltage difference causes electrons to flow in both antenna sections from n+-regions **908** of FIG. **10** to rectifier structure **905***a*. This is the first source of electron current in rectifier structure **905***a*. The second source of electron current in rectifier **905***a* is the electron current induced in the antenna by the magnetic field of the EM wave. This electron current has a magnitude that depends on the power of the incident EM wave. The direction of each source of electron currents at any given time is determined by the phase of the EM wave. In this configuration, the two sources provide electron currents to the dipole antenna. Maximum currents in both antenna sections occur at the center of the dipole antenna. The gap length D of antenna **904** is designed to be much smaller than ¼ the wavelength of the EM wave that antenna **904** is designed to receive. Ideally, each of antenna sections **904***a* and **904***b* is less than ¼ the wavelength of the EM wave being received. The magnitude of the current from n+-regions **908** is determined by the magnitude of the voltage difference and the magnitude of resistance between the junction of the n+-region and the contacting antenna section of the dipole antenna.

[0051] In this configuration, where the rectifier structure at the center of the dipole antenna is an NBD similar to that discussed for NBD **300** of FIG. **3**[1], the electron currents in the dipole antenna are shunted by the NBD **300** to the output channel (e.g., output channel **903**). Rectifier structure may be provided by other similar devices. As explained below, the NBD has a raised voltage at the output channel, thus the electron currents of multiple antennae are summed at electron output channel **903**. For example, on a dipole antenna as shown in rectenna array **900** of FIG. **9**, an electron current from electron input channel **902** flows to the n-regions (e.g., n+ regions **908** of FIG. **10**) surrounding the antenna sections, through the antenna sections to the NBD **300**s, and from there the electron current flows to electron output channel **903**. Thus, rectenna array **900** may be seen as a battery providing a voltage (i.e., the voltage across the NBD) between electron input channel **902** and electron output channel **903**. DC power is collected along the N-type channels diagonally and each center NBD of gap rectenna. Extra electrons are supplied by the connections of n-type channels diagonally at the ends of the antenna. The alternative embodiment shown in FIGS. **22**(*a*) and **22**(*b*) perform similarly.

---

[1] In this description, when a device requires a diode similar to NBD **300** discussed in FIG. **3**, the required diode is referred as "NBD **300**". Similarly, when a device requires a diode similar to NBD **600** of FIG. **6**, the required diode is referred as "NBD **600**".

[0052] FIG. **11** shows rectenna arrays **1101** and **1102** connected in series by connecting electron output channel **1104** of rectenna array **1101** to electron input channel **1105** of rectenna array **1102**. Thus connected, rectenna arrays **1101** and **1102** may be seen as a battery having a voltage that is twice the NBD voltage between electron input channel **1103** and electron output channel **1106**. In this manner, multiple rectenna arrays may be connected to provide a device having a voltage that is N times the NBD voltage, where N may be any positive integer greater than or equal to 1. Alternatively, rectenna arrays **1101** and **1102** may be connected together in parallel if they have the same output voltage, with electron input channels **1103** and **1105** connected together and electron output channels **1104** and **1106** connected together, to create a device having twice the current of an individual rectenna array.

[0053] As explained below, an NBD may be used to detect and rectify very high frequency signals. Accordingly, by detecting and rectifying very high frequency EM waves efficiently, the present invention provides a device for detecting and converting into DC power using frequencies of the EM spectrum that are hitherto impractical or impossible to use for a power conversion application, such as frequencies higher than the visible spectrum. The present invention finds applications in power conversion applications using a wide range of EM wave frequencies, such as infra-red (IR) and visible light (e.g., solar energy). The present invention may be utilized as a fast response photo-sensor in optical sensing and optical networks. The antenna in each rectenna element (or rectenna) can be any size and any shape of any type. A rectenna array can be configured out of many different rectenna elements. Also, each rectenna array can be different from the rectenna arrays of FIGS. **9** and **11**. The rectenna array of the present invention collects the electrons current flowing from all the input channels of the rectenna elements to all the output channels of the rectenna elements. The fully depleted region of an NBD is directly connected to the antenna.

[0054] The presence of a gap in each dipole antenna limits the highest frequency under which a rectenna (or a rectenna array) of the present invention may operate. According to one embodiment, a gapless dipole antenna is shown in top and side views in FIGS. **12**(*a*) and **12**(*b*), respectively. NBD **600** may be used as an input NBD for gapless dipole antenna, which is further discussed below in this detailed description. As shown in FIGS. **12**(*a*) and **12**(*b*), antenna **55** of dipole antenna **1200** is connected to two NBDs (formed by p-regions **53** and **54** and n-region **57**), forming an electron output terminal on one side, and to two NBDs (formed by p-region **56** and n-regions **51** and **52**), forming an electron input terminal on the other side. In other words, a rectenna element **1200** is formed by antenna **1200**, two NBDs for input at an electron input terminal and two NBDs for output at an electron output terminal. A voltage difference between the electron input terminal and the electron output terminal of a dipole rectenna element **1200** is provided by the sum of the voltages across the two NBDs. Thus, dipole antenna **1200** has a resolution of two NBDs, which is twice the resolution of dipole antenna **904** of FIGS. **9** and **10**. When an EM wave impinges on the antenna, a voltage difference is created between the ends of this antenna. The voltages at the opposite ends of the dipole antenna are of opposite polarities. The end of the antenna having the positive voltage will have electron flow induced from the input NBDs to the output NBDs because the resistance between NBD **300**s and the antenna **55** is very small. The input NBDs are provided for electron input. The output NBDs provide a rectifier structure. The input NBD directs the electrons from the electron input channels to the antenna. The output NBD serves as a rectifier structure for antenna signals. The output NBD has a forced depleted p-region that connects directly to antenna. NBD **300** may be used as an output NBD because the p-region that connects to the antenna section is a force depleted region. The output NBD is not required to have a forced depleted p-region, according to one embodiment of the present invention. A non-forced NBD[2] may be used. Unlike a forced depleted p-region, a non-forced depletion region does not rectify the electron current at forward bias. The n-region of an input NBD can be either a non-forced depleted region or a forced depleted region. The forced depleted input NBDs will build up electrons at forward bias and deliver better rectenna efficiency than the non-forced depleted input NBDs. N-region of NBD **600** is forced depleted and may be used as an input NBD for gapless rectenna design. N-region of non-forced NBD **600** is non-forced depleted and may be used as an input NBD for a gapless rectenna design. The fully depleted regions of input NBDs or output NBDs are directly connected to the antennae.

[0055] The phase of the EM wave determines which end of the antenna has an electron current. In this configuration, there is only one current source for the antenna (rectenna or rectenna element). The source of electron current is the p+-regions at the end of the antenna next to the input NBDs (e.g., p+-region **56** of FIGS. **12**(*a*) and **12**(*b*)). The magnitude of the current from the p+-regions is determined by the voltage difference and the resistance between the junction of the p+-region and the contacting antenna section of the gapless antenna. The DC voltage at both ends of antenna element **55** is equal to the NBD voltage, relative to either the input terminal or the output terminal or dipole rectenna element **1200**. The NBD can raise output voltage for signals at reverse bias. If the voltage induced by the EM wave on antenna **55** is within this input voltage range, then the voltage difference between antenna **55** and output n-channel **57** is raised. Therefore, a small signal of the EM waves may be rectified for suitable applications which were not achievable by other rectenna. DC power is collected by connecting the n-type channels under the output NBDs (p-regions **53** and **54** in FIG. **12**(*a*)). Extra electrons are supplied by the connections of P-type channels under the input NBDs. When two gapless antennae are lined up end to end with a separation distance D then this antenna pair will operate like a single gap antenna as described above. This is because the input NBDs at the far ends of the gapless antenna pair act like the gap antenna n+-type input channel and the two output NBDs in the center of the gapless antenna pair act as the center output NBD of the gap antenna.

[0056] FIG. **13** shows rectenna array **1300** including numerous gapless dipole antennae (e.g., antenna **1200** of FIG. **12**) with their respective electron input terminals connected together to form electron input channel **1302** and their respective electron output terminals connected to form output channel **1301**. Numerous such rectenna arrays may be connected in series or in parallel, as shown in FIG. **14**. As shown in FIG. **14**, electron output channel **1404** of rectenna array **1402** is connected serially with electron input channel **1403** of rectenna array **1401** through a metal trace (not shown) to provide current at twice the output voltage of the individual rectenna array. The metal trace prevents the electron input channel (p-type) and electron output channel (n-type) from forming a pn-junction, as a pn junction causes an undesirable voltage drop. Rectenna array **1401** and rectenna array **1402** can be connected in parallel by having electron input channels **1403** and **1406** connected together and electron output channels **1405** and **1404** connected together. Connecting two of the same rectenna arrays in parallel provides twice the current of an individual rectenna array.

---

[2] As discussed below, the term non-forced NBD refers to an NBD having a width in one region that is exactly equal to the depletion width of the corresponding conductivity type in an abrupt P-N junction of the same dopant concentrations.

[0057] Input device such as the NBDs provided for electron input may be provided by similar devices. Gapless rectenna element **1200** provides full wave rectification. In one embodiment, rectenna element may include an input NBD and an output NBD at two ends of the antenna for half-wave rectification. Alternatively, half-wave rectification may be achieved using either one input NBD (e.g., NBD **51**) and one output NBD (e.g., **53**), or one input NBD (e.g., NBD **52**) and output NBD (e.g., NBD **57**). In other words, a rectenna element is formed by antenna **1200**, either one NBD (e.g., NBD **51**) for electron input at an electron input terminal and one NBD (e.g., NBD **53**) for electron output at an electron output terminal, or one NBD (e.g., NBD **52**) for electron input at an electron input terminal and one NBD (e.g., NBD **57**) for electron output at an electron output terminal.

[0058] Gapless rectenna element **1200** collects current between the electron input channels and the output NBDs. Another gapless antenna **2200** utilizes two sources of current, similar to gap antenna **904**, according to another embodiment of the present invention. Dipole antenna **2200** is shown in top and side views in FIGS. **20**(*a*) and **20**(*b*), respectively. As shown in FIGS. **20**(*a*) and **20**(*b*), antenna **2205** of dipole antenna **2200** is connected to an NBD formed by p-regions **2203** and n-region **2204**, forming an electron output terminal on one side, and to an NBD formed by p-region **2201** and n-regions **2202**, forming an electron input terminal on the other side. The NBD formed by p-regions **2203** and n-region **2204** is a rectifier structure, in either of p-region **2203** and n-region **2204** can be a forced depleted region or non-forced depleted region. The NBD formed by p-region **2201** and n-regions **2202** drives electrons to the antenna **2205**, and may be implemented by an NBD, such as NBD **600** discussed below. A rectenna element includes antenna **2205**, an electron input terminal and an electron output terminal. DC power is collected by connecting n-type channels under the output NBD (e.g., n-regions **2204** in FIG. **20**(*a*)). Extra electrons are supplied by connecting p-type channels under the input NBD. The input terminals of rectenna elements are connected together and the output terminals of rectenna elements are connected together to form the rectenna array.

[0059] FIG. **21** shows gap rectenna arrays **2300** and **2350** connected in parallel in one package such that input channels and output channels are shared by both rectenna arrays. The sharing of input and output channels is shown in FIG. **21** by input channel **2302** and output channel **2309**. Rectifiers **2305***a* and **2355***a* output electrons to output **2309** and n-regions **2308** and **2358** receive electrons from input channel **2302**. Using this type of packaging provides a higher density design providing a way to increase the received EM wave bandwidth and power output. Non-gap rectenna arrays can also be arranged in parallel similarly. Full-wave rectification results from using a forced NBD in such an rectenna design. However, using a non-forced NBD achieves half-wave rectification. To perform a full-wave rectification using two half-wave rectifications, antenna **2304***a* and antenna **2304***b* each connects to a separate **2305***a* which connect to output channel **2309**, and antenna **2354***a* and antenna **2354***b* each connects to a separate **2355***a* which connect to output channel **2309**.

[0060] According to one embodiment of present invention, full-wave rectification can be achieved using an NBD for a gap dipole antenna, while half-wave rectification can be achieved using a non-forced NBD. According to one embodiment of present invention, full-wave rectification can be achieved by using either a forced or a non-forced NBD (e.g., NBD **300**) for rectifiers, but using a forced or non-forced NBD (e.g., NBD **600**) for electron input with gapless dipole antenna. Full-wave rectification may also be achieved by using two half-wave rectifications, according to one embodiment of the present invention.

[0061] Rectifier structures of the EM rectenna of the present invention may include different numbers and types of NBDs, according to one embodiment of the present invention. These NBDs of a rectifier can be connected in series, in parallel or both. Therefore, the rectifier structures of the EM rectenna can be in different configurations depending on the requirements of the desired result or performance. When the input voltage is varied within a predetermined negative bias voltage range of a NBD, the output voltage of a NBD may be higher than the input voltage by a substantially constant value. This means that the output voltage of an antenna can be raised by a DC voltage when the rectifier has serially connected NBDs. Similarly, the output current of an antenna can be regulated when rectifier has NBDs connects in parallel. By varying the output voltage or current, a variation of the EM rectennae can be provided to meet different needs and to achieve different efficiencies.

[0062] Rectifier structures of the EM rectenna of the present invention may use other devices for rectification instead of NBDs according to one embodiment of the present invention. Other rectifying devices include Schottky diodes, back diodes and tunnel diodes. Suitable rectifier devices would be any device that conduct appreciatable current in one bias direction. Any device which have rectifier qualities as described above are within the scope of this invention.

[0063] The present invention uses semiconductor material (i.e. n-type and p-type material) for electron input and output channels instead of traditional higher conductive metallic material. Semiconductor material was chosen to reduce interference between electron channels and antennae, especially in highly packed antennae structures as discussed above.

[0064] Since each antenna gathers electromagnetic waves at a frequency consistent with its size and shape, and the diode (i.e., the rectifier structure) rectifies that energy into a D.C. current. As in both gap and gapless rectenna embodiments of the present invention, each rectenna element can be any size and any shape, and can be provided by any antenna type. A rectenna array can be made out of many different rectenna elements. The present invention is not limited to a dipole rectenna design, nor to the full-wave rectifying rectenna described above. According to another aspect of the present invention, an NBD capable of rectifying a small-amplitude, high frequency signal is provided, which is suitable for use in conjunction with the energy conversion device described above. This NBD is a “forced depletion” natural breakdown device, as explained below, according to one embodiment of the present invention.

[0065] The present invention referred a p-type or n-type region as fully depleted when the whole region is depleted of its respective majority carriers. This region may include different materials in any forms, shapes, dimensions, conductivities or concentrations.

[0066] The present invention referred a p-type or n-type region as fully depleted when the whole region is depleted of its respective majority carriers. This region may include different materials in any forms, shapes, dimensions, conductivities or concentrations. The doping level and other parameters may be varied independently to achieve the desired results. Although the examples and drawing shown herein for NBDs shown regions of homogeneous dopant concentrations, such regions are only provided for illustration purpose only. The present invention is equally applicable in devices where the dopant concentrations are non-homogeneous.

[0067] According to one embodiment of the present invention, a NBD type diode includes a semiconductor (say, p-type region) that has a width w_p that is less than or equal to the depletion width x_p of a conventional abrupt pn-junction without an externally imposed voltage. That is:

$$w_p \leq w_p = \sqrt{\frac{2\varepsilon_s N_D \phi_i}{q N_A (N_A + N_D)}}$$

[0068] where ϵ_s the electrical permittivity of silicon, q is the charge of an electron, ϕ_i is the "built in" potential of the pn junction, N_A and N_D are the doping concentrations of p-region **101** and n region **102**, respectively. As mentioned above, when $w_p = x_p$ ($w_n = x_n$), the region is referred to as a non-forced depleted region, and when $w_p \leqq x_p$ ($w_n \leqq x_n$), the region is referred to as a forced depleted region

[0069] FIG. **3** is a schematic representation of NBD **300**, according to one embodiment of the present invention. As shown in FIG. **3**, NED **300** includes p-region **301** and n-region **302**, with p-region **301** having a width w_p, which is less than or equal to the depletion width x_p of a corresponding depletion width in the p-region side of a conventional pn junction. (A semiconductor region having a depletion width that is less than the depletion width for the corresponding semicondcutor type in a conventional pn junction is referred herein as having a "forced depletion" width). In contrast, the width of n-region **302** may be smaller than, greater than or equal to the conventional depletion region x_n for the n region of a conventional pn junction diode of comparable doping concentrations. One embodiment of the present invention is a forced depletion condition on p-region **301**, and n-region **302** having a width greater than x_n. Also shown are contact regions **303** and **304** which are contacts to allow NED **300** to be connected to an electronic circuit. The doping concentrations in p region **301** and n-region **302** are sufficiently high such that contacts **303** and **304** are ohmic contacts. Contact region **303** and **304** may be formed, for example, by depositing a conventional interconnect conductor, such as aluminum or copper, using conventional chemical vapor deposition techniques, or other means known to those skilled in the art. P region **301** and n region **302** may be formed in a conventional silicon substrate using ion implantation, or other means known to those skilled in the art.

[0070] Width w_p of an NBD **300** may be calculated based upon the doping concentration. The predetermined width w_p for NBD **300** may be calculated using the following steps:

[0071] (1) First choose doping concentrations for a p-region and an n-region of a conventional PN junction diode such that, under the zero applied bias voltage, the p-region has a depletion width X_p between point **4** and point **3** and the n-region has a depletion width X_n between point **3** and point **2**, as shown in FIG. **3**. These dimensions create a built-in voltage V_D volts in the conventional pn junction diode. In an NBD, the built-in voltage V_{FD} is less than V_D. Voltage V_{th} is the threshold voltage for the conventional pn junction diode. The Fermi level of the NBD at zero applied bias voltage is shifted towards the Fermi level of the intrinsic semiconductor and away from the equilibrium Fermi level of a conventional pn junction diode.

[0072] (2) Select a voltage V_s, which is the maximum forward bias voltage that can be applied on NBD **300** before the region that is fully depleted at zero applied bias voltage ceases to be fully depleted. A number of desired features (e.g., constant tunneling current at low forward bias voltage, charge storage, voltage range of tunneling) may be achieved by the NBD between zero applied bias voltage and voltage V_s, depending on the application of the NBD. When the applied bias voltage is increased from zero towards voltage V_s, the Fermi level of the NBD is decreased towards the Fermi level of the conventional pn junction diode. However, if the applied bias voltage is decreased in this range, the Fermi level maintains a constant level, so that a charge is accumulated in the n-type region as the applied voltage decreases from V_s to zero.

[0073] As the value of voltage V_s is between zero and the conventional pn junction diode built-in voltage V_D, the voltage across the pn-junction is given by $V_x = V_D - V_S$. In one embodiment of the present invention, the value of voltage V_S is selected to be close to the built-in voltage $V_D (V_S \sim V_D)$. The width of the fully depleted depletion region required to achieve this condition is very thin. In another embodiment of the present invention, the value of V_s is not selected to be close to V_D. According to one embodiment of the present invention, the value of V_s can be tuned or selected to accommodate an active voltage range for the NBD operation. The depletion width of NBD **300** remains unchanged as long as the applied bias voltage is less than V_S. As explained above, when an applied bias voltage on an NBD is between zero and V_s, a charge is accumulated. An NBD with a smaller V_S stores less charge than an NBD which has a larger V_S.

[0074] (3) Calculate the depletion width w_p of p-region **301** such that, when voltage V_s is imposed on **303** toward p-region **301**, the whole p-region **301** remains depleted. Assuming an abrupt junction approximation, the width w_p may be calculated using the following equation:

$$x_p = \left[\frac{\frac{kT}{q}\ln\left[\frac{N_D N_A}{n_i^2}\right] - V_S}{\frac{e}{2\varepsilon_S}\left(\frac{N_A^2 + N_A N_D}{N_D}\right)}\right]^{\frac{1}{2}}$$

[0075] There are other ways to calculate w_p as known by those skilled in the art. The built-in voltage V_{FD} of the NBD **300** equals to—($V_D - V_S$) volts. If $w_p = x_p$, V_s is zero volts.

[0076] Note that the width w_p is calculated above using an abrupt junction approximation. Other suitable methods may also be used. The width w_p may be calculated using different junction approximations, depending on the application. As explained above, the condition $w_p < x_p$ is referred to as a "forced depletion condition" and, under such a condition, p-region **301** is referred to as a "forced depletion region", according to one embodiment of the present invention. When p-region **301** is in a forced depletion condition, the value of V_S is not equal to zero. The condition $w_p = x_p$, is referred to as a "non-forced depletion condition" and, under such a condition, p-region **301** will be referred to as a "non-forced depletion region", according to another embodiment of the present invention.

[0077] When p-region **301** is in non-forced depletion condition, the value of V_S is equal to zero. Once w_p is determined, an NBD **300** with the p-region **301** fully depleted between contact region **303** and n-region **302** may be created with different width of n-region **302**. W_n is the depletion region width of n-region **302** on NBD **300**. The width of n-region **302** may range from w_n to larger than x_n. The difference in the width of n-region **302** creates variations for the NBD **300**. NBDs can be created having a width for n-region **302** greater than x_n. When the external voltages applied to contacts **303** and **304** is zero (zero applied voltage bias or without bias), p-region **301** of NBD **300** is fully depleted. One embodiment of the invention provides a forced depletion condition on p-region **301** with the w_P is less than x_p and the width of n-region **302** being a value between w_n to larger than x_n. One embodiment of the invention is a non-forced depletion condition in which p-region **301** with a w_p equal to x_p and the width of n-region **302** may range from w_n to larger than x_n.

[0078] When the applied bias voltage is less than zero volts, even by a small amount, the accumulated charge is relaxed. Thus, the NBD is conducting under a reversed bias condition.

[0079] Alternatively, the forced or non-forced depletion region dimensions can be obtained by starting with the dimensions of a conventional pn-junction, and adjusting the dopant concentrations of the p-region and n-region such that the width of one of the region ("first region") is exactly equal to its depletion region (non-forced depletion condition), if the regions form a conventional pn-junction, or further increasing the concentration of the other region, such that the width of the first region is now less than its expected depletion width, calculated as if the regions form a conventional pn-junction.

[0080] In another embodiment of the present invention, shown in FIG. **6**, n-region **602** may also be put under a forced depletion condition without a forced depletion or non-force depletion in p-region **601**, NBD **600** variations. An NBD can have more than one fully depleted region. The differences in the width of p-region **601** create variations for NBD **600**. One embodiment of the invention provides a non-forced depletion n-region **602** (i.e., a w_n that is equal to x_n) and a width of p-region **301** between w_p to larger than x_p. The differences in the width of p-region **601** create variations for this embodiment. Another embodiment of the invention provides a forced depletion condition on n-region **602** with the w_n is smaller than X_n and the width of p-region **301** may range from w_p to larger than x_p, according to this embodiment. The differences in the width of p-region **601** create variations for this embodiment. These variations of NBD are natural breakdown diodes. An NBD can have more than one fully depleted region. Each of these regions can be either a forced depletion region or a non-forced depletion region.

[0081] An NBD has one of the p-region or n-region fully depleted under zero biasing. NBD **300** has p-region **301** in a forced depletion condition and an n-region **302** with its width larger than x_n. The operations of NBD **300** are explained with respect to an external applied bias voltage under following conditions:

[0082] a) When a zero forward bias voltage is applied on NBD (i.e., at zero bias), the input voltage is V_{IN}, (i.e., $V_{IN}=0$).

[0083] b) When a forward bias voltage is applied on NBD **300** between 0 and V_s (i.e., $0<V_{IN}<=V_S$).

[0084] c) When a forward bias voltage applied on NBD **300** is between V_s and V_{th} (i.e., $V_s<V_{IN}<V_{th}$).

[0085] d) When a forward bias voltage applied on NBD **300** is larger than V_{th} (i.e., $V_{IN}>V_{th}$).

[0086] e) When a reverse bias voltage V_{IN} is applied on NBD **300**.

[0087] Accordingly, (a) When $V_{IN}=0$, an electric field (referred to as the "secondary electric field") with a voltage difference of V_s is created along the edge of the depletion region in n-region **302**. No current flows in the device. The voltage difference between the depletion region electric field and the built-in potential is V_s.

[0088] (b) When V_s is selected to be not close to V_D, $0<V_{IN}<=V_s$ and V_{IN} is applied at contact **303** on NBD **300**, the depletion width in p-region **301** remains the entire width of p-region **301** because V_{IN} is smaller than the voltage potential across the secondary electric field in n-region **302**. As V_{IN} increases, the Fermi level between the depletion region and the equilibrium Fermi level between the p-region **301** and n-region **302** decreases. As the applied bias voltage V_{IN} increases, the secondary electric field strength decreases in n-region **302**. Once V_{IN} reaches V_s, the secondary electric field in n-region **302** becomes zero. NBD **300** responds to a signal change faster than a conventional pn junction, so that NBD **300** is suitable for rectifying high speed signals. This fast response time characteristic is present in all NBDs. A device that utilizes NBD concepts will have a faster response time than the same device not utilizing NBD concepts.

[0089] When V_s is selected to be close to V_D, for an applied bis voltage V_{IN} less than V_s (i.e., $0<V_{IN}<=V_s$), a constant forward current flows in NBD **300** due to tunneling through the sufficiently thin depletion region. The depletion width in p-region **301** remains the entire width of p-region **301**.

[0090] (c) When the applied bias voltage V_{IN} is between V_s and the threshold voltage (i.e., $V_S<V_{IN}<Vth$), the depletion widths in both p-region **301** and n-region **302** reduce. The voltage drop across the depletion regions reduces also. In this regime, a small forward leakage current proportional to V_{IN} flows in NBD **300**. As V_{IN} becomes very close to V_{th}, the depletion width in NBD **300** becomes significantly small to allow a significant current to flow.

[0091] (d) When the applied voltage V_{IN} exceeds the threshold voltage (i.e., $V_{IN}>=V_{th}$), NBD **300** conducts current.

[0092] (e) When a reverse bias voltage V_{IN} is applied to NBD **300**, the depletion width remains the same. As the reverse bias voltage increases the reverse current increases substantially linearly based upon the resistance between contact **303** and p-region **301** and the resistance between contact **304** and n-region **302**.

[0093] (f) When reversed biased, NBD **300** operates as a majority carrier device (electrons being injected in to the n-region) as apposed to a minority carrier device when forward biased. The switching times of majority carrier device are typically faster than switching times of minority carrier device.

[0094] FIG. **5** is a plot of the current versus voltage (IV) characteristics of NBD **300**, when V_s is selected not to be close to V_D. NBD **300** can conduct appreciable reverse current when input voltage is negative and conduct forward current when input voltage is larger than V_{th}. NBD **300** conducts a negligible leakage current when the bias voltage is between 0 and V_{th}. When a forward bias voltage between 0 and V_s is applied to an NBD, the depletion region width does not change as long as the Fermi level of the device is greater than the depletion region Fermi potential. This behavior is illustrated by FIG. **4** which shows the relationship between NBD **300** depletion region voltage V_{FD} and the input voltage V_{IN}, where the behavior of the depletion width is also shown. FIG. **24** is a plot of the current versus voltage (IV) characteristics of NBD **300**, when V_S is selected to be very close to V_D, where a constant forward current due to tunneling is shown for an applied bias voltage between 0 volts and V_s.

[0095] In one embodiment the width of NBD **300** p-region for creating a constant current is calculated by the following:

[0096] 1) Using the IV curve of a conventional diode utilizing the same materials and doping concentrations for NBD device, find forward bias voltage that matches desired current on curve. The bias voltage needs to be less than V_{th}. This bias voltage will be the V_s value.

[0097] 2) Determine width of depletion band of p-region in conventional diode when conventional diode is biased at V_s determined in step 1). This can be done through calculation or simulation of device as known by those skilled in the art. This width is W_P.

[0098] 3) Create an NBD with a p-region of width W_p as determined in step 2) using the same material and doping concentration of conventional diode used in step 1).

[0099] An NBD device behaves asymmetrically for an increasing applied bias voltage between 0 volts and voltage Vs and a decreasing applied bias voltage over the same voltage range. As the applied bias voltage increases, the Fermi level of the device decreases, so that the secondary electric field decreases. However, when the applied bias voltage decreases over the same range, a third electric field appears at the secondary electric field edge in the n-region **302** neutral region, which continues to increase without causing a change in the Fermi level. If the bias voltage is again increased, this third electric field decreases. Once the applied bias voltage becomes negative, the charge in the third electric field is released, thereby causing a reverse current surge. The maximum voltage across the third electric field is V_s. Therefore, applying a negative bias voltage after applying a positive bias voltage on NBD **300** would result in a reverse current.

[0100] Another embodiment of the present invention has a forced depletion condition on p-region **301** and an n-region **302** with its width less than X_n where the depletion band width does not completely cover n-region **302**. The behavior of this device is the same as NBD **300** described above. For the situation when a forced depletion condition is created, the depletion width of n-region **302** covers the whole n-region **302** between contact **304** and complete depleted p-region **301**, ("NBD **310**"): The behavior of NBD **310** under condition (a) of $V_{IN}=0$ is the same as described above. The behavior of NBD **300** under condition (b) when $0<V_{IN}<=V_S$, status is the same as described above until the n-region **302** becomes fully depleted. Once n-region **302** is fully depleted, NBD **300** reaches condition (c) prior to $V_{IN}=V_s$. The behavior of NBD **300** under condition (c) is the same as described above.

[0101] When a NBD **300** is connected in series to a current source (i.e. a signal from an antenna or sensor), a voltage appears across NBD **300**. Since NBD **300** conducts current at reverse biased voltage, a negative voltage potential appears when a current source imposes a reverse bias current.

[0102] Thus, NBD **300** can provide a small positive current when a positive bias voltage V_{IN} less than V_s is applied (i.e., $0<V_{IN}<=V_s$) is applied at contact region **303**. NBD **300** can also rectify negative input signals (i.e., $V_{IN}<0$). NBD **300**, with the capability of storing charge between $0<V_{IN}<=V_s$, and conducting a reverse current at reverse bias, can rectify very high frequency signals, within the regime from V_s to $-V_s$ and negative voltage signals.

[0103] Another embodiment of the present invention provides a forced depletion p-region **301** and a forced depletion n-region **302** (i.e., having a width less than x_n). The behavior of NBD is the same as NBD **300** described above.

[0104] Another embodiment according to the present invention has a non-forced depletion width (i.e., $w_p=x_p$ or $w_n=X_n$). In this configuration, the resulting NBD is conductive at reverse bias. A non-forced NBD has the same reverse bias characteristics of an NBD **300**. However, when a forward bias voltage is applied on a non-forced NBD, its current and voltage characteristics are the same as those of a conventional pn junction diode.

[0105] To summarize, an NBD of the present invention allows a conductive current flow when a reverse bias voltage applied.

[0106] If an NBD and a current source are connected in series, the output voltage appears across the NBD. By selecting a value of V_s at forward bias, NBD may be provided desirable features such as charge storage and constant current. If the applied bias voltage exceeds the threshold voltage, the NBD provides a conductive current. NBD **300** stores charge by a decreasing applied bias voltage between 0 volts and V_s; the stored charge is released when applied bias voltage becomes negative. Thus, an NBD can full wave rectify even a small sinusoidal signal, thus is suitable for applications such as solar energy generation. The application of the NBD invention to conventional PN junction diodes created two new active bias voltage ranges, namely the reverse bias voltage and forward bias between zero and Vs volts. These two new active regions enable NBD modified PN junction diodes to have three active regions to be utilized for applications.

[0107] An NBD does not have a breakdown voltage. As one of the regions of a pn junction is fully depleted, no leakage current is observed even under a reverse bias condition. The built-in electric field provides high conductivity at reverse bias by zeroing the distance for electrons and holes to travel across the pn-junction to the opposite region. A reverse current flows when the applied bias voltage V_{IN} is negative (i.e., $0>V_{IN}$). Constant current or charge storage at forward bias can be provided by a non-zero V_s value, depending on the application.

[0108] FIG. **23** shows the IV curve of NBD **300** when contact resistance is very low, according to one embodiment of present invention. In this embodiment, the IV curve is very close to the ideal diode IV curve. Because the value of V_s is not equal to zero, the NBD **300** will have charge stored when forward bias decreasing toward zero volts. This charge will be released when the NBD **300** is reverse-biased and creates a reverse current surge. The NBD **300** may be considered as an ideal diode with reverse current surge capability. In FIG. **23**, when $V_S=0$, the IV curve is the same as the IV curve of non-forced NBD **300** with very low contact resistance, according to one embodiment of present invention. The non-forced NBD **300** may be considered as an ideal diode with a breakdown voltage at the forward threshold voltage.

[0109] According to another embodiment of the present invention, as discussed above, FIG. **6**(*a*) shows NBD **600** with n-type region **602** having a width w_n that is less than x_n—the depletion width of a conventional pn junction diode:

$$w_n \le x_n = \sqrt{\frac{2\varepsilon_s N_A \phi_i}{qN_D(N_A + N_D)}}$$

[0110] A similar determination provides width W_n for NBD **600**. The operation of a forced depletion condition with n-region **602** with its depletion band width $w_n<X_n$ and p-region **601** larger or equal to x_p behaves as follows:

[0111] At (a) zero applied bias voltage, no current flows in the device. As $W_n<x_n$, an excess number of holes builds up along the edge of the depletion region in p-region **601**, thereby creating a secondary electric field. The voltage potential across this secondary electric field is V_s.

[0112] At (b), when voltage V_s is selected not to be close to V_D and the applied bias voltage is between 0 volts and V_s (i.e., $0<V_{IN}<=V_S$), n-region **602** remains fully depleted. As the applied bias voltage V_{IN} increases, the secondary electric field decreases. Once V_{IN} equals V_s, the secondary electric field in p-region **601** becomes zero. Thus, NBD **600** responds to a signal change faster than a conventional pn junction because the secondary electric field width is smaller than the depletion width of a conventional pn junction. Thus, NBD **600** is suitable for rectifying high speed signals.

[0113] When voltage V_s is selected to be close to V_D and for an applied bias voltage between 0 volts and V_s (i.e., $0<V_{IN}<=V_s$), a constant forward current due to tunneling through the sufficiently thin depletion region. N-region **602** remains fully depleted the entire width of n-region **602**.

[0114] (c) When the applied bias voltage is between V_s and the threshold voltage (i.e., $V_S<V_{IN}<V_{th}$), the depletion widths in both p-region **601** and n-region **602** reduce. The current in the device is a small forward leakage current that is proportional to V_{IN}. The output voltage is V_{IN}-V_D. When V_{IN} is very close to V_{th}, the depletion width on NBD **600** is significantly small for conductive current to flow.

[0115] (d) When the applied bias voltage exceeds the threshold voltage (i.e., $V_{IN}>=V_{th}$), NBD **600** conducts current.

[0116] (e) When a reverse bias voltage V_{IN} is applied to NBD **600**, the depletion width remains the same. As the reverse bias voltage increases the reverse current also increases substantially linearly.

[0117] NBD **600** has the same current versus voltage characteristics as NBD **300**. NBD **600** also stores charge under a forward-biased voltage between 0 and V_s in the same way as NBD **300**. Also, like the NBD **300**, when NBD **600** is connected in series to a current source a voltage appears across NBD **300**.

[0118] Another embodiment according to the present invention provides $w_n=x_n$ (i.e., the non-forced depletion condition). Non-forced NBD **600** has the same behavior as a non-forced NBD **300**.

[0119] According to one embodiment of the present invention, FIG. **6**(*b*) shows an NBD having two regions (p-region and n-region) which are both under forced depletion condition. According to other embodiments of the present invention, FIGS. **7**(*a*), **7**(*b*) and (*c*) show different NBD configurations, represented by NBD **700**, NBD **710** and NBD **720**, each including a region (e.g., **701**, **711**, **721** or **722**) under the forced depletion condition. Also, when region **702** is p-type and region **712** is n-type, then NBD **700** and NBD **710** can be seen as NPN and PNP transistors respectively. FIGS. **8**(*a*), **8**(*b*), **8**(*c*), **8**(*d*) and **8**(*e*) show different NBD configurations **800**, **810**, **820**, **830** and **840** each including a region (e.g., **801**, **811**, **821**, **822**, **831**, **832**, **833**, **841**, **842**, and **843**) having two or more doping concentrations under forced depletion conditions. FIGS. **15**(*a*) to **15**(*d*), **16**(*a*) and **16**(*b*) show some of the embodiments of the NBD, according to the present invention.

[0120] FIGS. **17**(*a*) to **17**(*f*) show some NBDs at a zero applied bias voltage, each having a forced depletion p-region (or n-region) formed adjacent to a Schottky barrier or an ohmic contact. The Schottky barrier or ohmic contact imposes a fully depletion p-region or a fully depletion n-region. Each of these fully depleted region may be considered non-forced or forced depleted regions.

[0121] FIG. **18**(*a*) shows NBD **1800** at a zero applied bias voltage, and conductors **1801** and **1803** which are contacts provided for connecting NBD **1800** to an electronic circuit. In NBD **1800**, n-region **1802** is fully depleted under a forced depletion condition, having a width less than depletion width **1804**. The doping concentration in n-region **1802** is sufficiently high such that the junction between conductor **1803** and n-region **1802** is an ohmic contact and conductor **1801** forms a Schottky barrier to n-region **1802**. NBD **1800** under reverse bias voltage performs substantially in the manner described above for NBD **600**, having the characteristics such as fast switching, conducting at a reverse bias, and a reverse voltage when connected with a current source in series. NBD **1800** under forward bias performs substantially the same as a conventional n-type Schottky diode under forward biased utilizing comparable materials. The forced depletion width described above for the pn junction configuration may be applied to determine the forced depletion width of a fully depleted p-region **1812** (or n-region **1802**).

[0122] FIG. **18**(*b*) shows NBD **1810** at a zero bias, and conductors **1811** and **1813**, which are contacts providing for connecting NBD **1810** to an electronic circuit. P-region **1812** is fully depleted under a forced depletion condition, so that the width of p-region **1812** is less than depletion widths **1814**. The doping concentration in p-region **1812** is sufficiently high, such that the junction between conductor **1813** and p-region **1812** is an ohmic contact, and conductor **1811** forms a Schottky barrier to p-region **1812**. NBD **1810** when reverse biased performs substantially in the manner describe above for NBD **300**, having characteristics such as fast switching, conducting at reverse bias, and a reverse voltage when connected with a current source in series. NBD **1810** under forward bias performs substantially the same as a conventional p-type Schottky diode under forward biased utilizing comparable materials.

[0123] To determine a forced depletion width for NBD **1800**, (1) a depletion width x_n, built-in voltage V_D and threshold voltage V_{th} of a conventional Schottky diode are determined using an n-region doping concentration at a zero bias, (2) a forward-bias work voltage V_s that is between zero and V_{th} is selected that can be used with Schottky diode **1800**, and (3) the depletion width w_n of n-region **1802** is calculated such that, when a forward bias voltage V_s is applied on NBD **1800**, n-region **1802** remains depleted with a built-in voltage V_{FD} that is equal to $-V_x$ (V_x is given by $V_x=V_D-V_s$). Regions **1802** and **1812** include, respectively, multiple p-type and n-type sections of different doping concentrations. According to another embodiment of present invention, an NBD may also be formed using three semiconductor regions, one or more of which is fully depleted. For example, all three regions may be fully depleted. A transistor having at least one fully depleted semiconductor region is an NBD within the scope of the present invention, which may used, for example, in conjunction with the rectenna described above.

[0124] According to another embodiment of the present invention, FIG. **19**(*c*) shows NPN bipolar device **2020** with no external voltages being applied. Device **2020** has n-type region **2026** fully depleted, p-type region **2025** sufficiently large to have a neutral region between depletion regions **2027** and **2028** and n-type region **2024** sufficiently large to have a neutral region between depletion region **2028** and contact **2023**. The p-type region **2025** (neutral region) is sufficiently large to prevent overlap of minority diffusion from depletion regions **2027** and **2028**. Device **2020** is considered a forced depleted device when n-type region **2026** is forced depleted and is considered non-forced depleted device when n-type region **2026** is non-forced depleted. Device **2020** is considered a conventional device when n-type region **2026** has a neutral region between contact **2021** and depletion region **2027**.

[0125] FIG. **28** shows IV curves **2801**, **2802** and **2803** for a conventional device, a non-forced depleted device and a forced depleted device respectively. IV curves **2801**, **2802** and **2803** are exaggerated and provided only for illustration purposes only. The bias voltage is with respect to fully depleted n-type region **2026** therefore forward biasing device **2020** would be to have contact **2023** at a positive voltage relative to contact **2021**. When device **2020** is a conventional device, a forward bias decreases the depletion region **2027** width and depletion region **2028** width increases. From IV curve **2801**, as the forward bias increases across conventional device **2020** current remains small and constant (i.e. leakage current) until depletion region **2027** conducts and depletion region **2028** width increases sufficiently so that its minority diffusion reaches depletion region **2027**. As the forward bias is further increased across device **2020** (conventional), the current increases until depletion region **2028** reaches depletion region **2027** where current increases exponentially. TV curve **2801** is based on device **2020** being conventional and having n-type region **2024** and n-type region **2026** each having the same neutral region width. Therefore, when device **2020** is conventional, it has similar characteristics reverse biased as forward biased in that depletion region **2028** width decreases and depletion region **2027** width increases.

[0126] Comparing a non-forced depleted device IV curve **2803** to conventional device TV curve **2801**, it can be seen that during forward biasing both devices behave similarly except during reverse biasing the non-forced depleted device has exponential increase in current at a smaller voltage magnitude then the conventional device. This behavior can be understood by the fact that a non-forced depleted region behaves the same as a conventional region when forward biased but conducts immediately when reverse biased, as explained above. Therefore when non-forced depleted device is reversed biased exponential increase of reverse current will occur as soon as depletion region **2028** start having exponential increase in current instead of when depletion regions **2027** and **2028** contact each other.

[0127] Comparing forced depleted device IV curve **2802** to conventional device IV curve **2801**, it can be seen that there are differences in both forward biasing and reverse biasing. As explained above, a forced depleted region behaves differently during increasing forward biasing verses decreasing forward biasing. During increasing forward biasing between zero and V_s depletion region **2027** width remains the same until, depletion region **2028** width increases and the n-type region **2026** Fermi level moves toward its non-forced Fermi level. During decreasing forward biasing between zero and VS depletion region **2027** width remains the same and depletion region **2028** width also remains the same. This is due to the potential voltage created across p-type region **2025** neutral region maintaining the same potential voltage between p-type region **2025** and n-type region **2024**. After an increase or decrease forward bias cycle between zero and V_s, the threshold voltage for the n-type region **2026** or p-type region **2025** junction will be reduced by V_s volts. Also after this forward bias cycle depletion region **2028** will be increased (i.e. the threshold voltage increased) by V_s volts. It can be seen that a voltage of V_s has been transferred from a threshold voltage in forced depleted region (i.e. n-type region **2026**) to a threshold voltage in an adjacent semiconductor region (i.e. p-type region **2025**).

[0128] IV curve **2802** shows the IV characteristics for forced depleted device **2020** after an increasing/decreasing forward biasing between zero and V_s. The reduced threshold voltage in forced depleted n-type region **2026** means during forward biasing current will flow across depletion region **2027** at a lower voltage than either the non-forced depleted device and conventional device. Also, during forward biasing, exponential current increase occurs at a lower voltage due to the increase width of depletion region **2028**. At reverse bias the increased width of depletion region **2028** requires a larger negative bias before exponential current will occur.

[0129] A fully depleted region within a NBD of the present invention will obey the following rules:

[0130] 1) If the fully depleted region is forced depleted, then at thermal equilibrium the Fermi level in the forced depleted region will adjust toward the intrinsic semiconductor Fermi level by the amount necessary to create a net zero current through the device.

[0131] 2) A voltage difference in neutral regions adjacent to fully depleted regions is created before the fully depleted region's Fermi level is adjusted toward the intrinsic semiconductor Fermi level.

[0132] 3) A fully depleted region's Fermi level will adjust toward its original level before voltage differences are created in neutral regions adjacent to the fully depleted region.

[0133] Based on the above rules characteristics for forced depleted regions within a NBD are as follows:

[0134] At thermal equilibrium prior to any bias voltage:

- **[0135]** The forced depleted region's Fermi level is forced toward the semiconductor intrinsic level. The voltage associated to this energy shift is V_s.
- **[0136]** All depletion regions within fully depleted regions will have reduced widths compared to non-fully depleted and conventional region of same material as fully depleted region.

[0137] During increasing forward bias between zero and V_s:

- **[0138]** The forced depleted region's Fermi level moves toward its original Fermi level.
- **[0139]** Depletion regions associated with the forced depleted region maintain there same widths.

[0140] During decreasing forward bias between zero and V_s:

[0141] If there are no adjacent neutral regions to the forced depleted region, then the forced depleted region's Fermi level moves toward intrinsic level.

[0142] If there are no depletion regions which can increase in width within adjacent neutral regions to the forced depleted region then charge will build up in adjacent neutral regions. The forced depleted region's Fermi level will stay the same. Depletion regions associated with the forced depleted region maintain there same widths.

[0143] Any depletion region which can increase in width within adjacent neutral regions to the forced depleted region will increase in width. Built-in potentials associated with the forced depleted region will be reduced making their threshold voltages lower. The forced depleted region's Fermi level stays the same. Depletion regions associated with the forced depleted region maintain their same widths.

[0144] During reverse bias:

[0145] If the device has only one depletion region, then the device will conduct at near zero bias (no threshold voltage), any charge storage due to decreasing forward biasing is immediately released, the forced depleted region's Fermi level moves toward its semiconductor intrinsic level until reaching the thermal equilibrium level. The depletion region in forced depleted region creates a negative potential voltage through device.

[0146] If the device has more than one depletion region, then the device will have a reverse threshold voltage (i.e. a breakdown voltage). Any charge stored stays until the device conducts a reverse current. The forced depleted region adds a negative potential voltage when the device is conducting reverse current.

[0147] Based on the above rules characteristics for non-forced depleted regions within a NBD are as follows:

[0148] Thermal equilibrium

[0149] The same as when utilizing a non-fully depleted region.

[0150] Forward bias increasing

[0151] The same as when utilizing a non-fully depleted region.

[0152] Forward bias decreasing

[0153] The same as when utilizing a non-fully depleted region.

[0154] Reverse bias

[0155] If the device has only one depletion region, then the device conducts at near zero bias (no threshold voltage). The depletion region in non-forced depleted region creates a negative voltage through device.

[0156] If the device has more than one depletion region, then the device has a reverse threshold voltage (breakdown voltage). The non-forced depleted region adds a negative voltage when the device is conducting a reverse current.

[0157] FIGS. **27.1** to **27.4** show a table of NBD structures with their expected characteristics. The first column on the left side of the table is the structure of the NBD as if the structure where laid out in linear manner. The terms used to indicate the structure are the following:

[0158] "Sch"—Contact-Semiconctor Schottky barrier

[0159] "Ohm"—Contact-Semiconductor Ohmic barrier,

[0160] "N non-F"—Non-forced depleted n-type region

[0161] "P non-F"—Non-forced depleted p-type region

[0162] "N Forced"—Forced depleted n-type region

[0163] "P Forced"—Forced depleted p-type region

[0164] "N"—n-type region with a neutral region

[0165] "P"—p-type region with a neutral region

[0166] The second column of the table indicates whether or not the fully depleted region has its Fermi level adjusted toward the semiconductor intrinsic level. A forced depleted region has its Fermi level adjusted (i.e. "Yes") while a non-forced depleted region does not (i.e. "No"). The third and forth columns define the characteristics that the structure has during increasing and decreasing forward biasing respectively. Terms used in these columns are the following:

[0167] "->Efn"—Indicates that the Fermi level of fully depleted region moves toward its original Fermi level prior to being fully depleted.

[0168] "->Efn"—Indicates that the Fermi level of fully depleted region moves towards the semiconductor intrinsic level.

[0169] The fifth column indicates whether or not the NBD structure conducts a reverse current at near zero reverse bias with a reverse potential across structure. The sixth column indicates whether or not the structure maintains the same bias voltage to conduct current (i.e. threshold voltage) after biasing the structure. A "No" means that after an increasing forward bias followed by a decreasing forward bias (a forward bias cycle) that one or more junctions have a different potential barrier then prior to the forward cycle.

[0170] According to another embodiment of the present invention, FIGS. **19**(*a*) and **19**(*b*) show NPN bipolar transistors **2000** and **2010** with no external voltages being applied. As shown in FIG. **19**(*a*), NPN bipolar transistor **2000** has a fully depleted n-type region **2006** which may function either as an emitter or as a collector for NPN bipolar transistor **2000**. FIG. **19**(*b*) shows NPN **2010** having fully depleted n-type regions **2014** and **2016** as an emitter and a collector, respectively. Different transistor characteristics may be achieved using one or more different semiconductor regions that are under a forced or non-forced depletion condition. For example, depleted regions **2006**, **2014** and **2016** in NPN transistors **2000** and **2010** may be put under forced or non-forced depletion conditions. Base P-type regions **2005** and **2015** may also be made fully depleted. PNP bipolar transistor structures may also be formed according to principles described for NPN transistors **2000** and **2010** above.

[0171] The behaviors of NPN and PNP transistors change when one or more of their semiconductor regions are completed depleted. Using NPN transistor **2000** configured in a common-emitter configuration (i.e. with emitter terminal **2003** grounded) as an example, when emitter region **2006** is fully depleted, a current flows from emitter region **2006** to base region **2005** (i.e. electrons flow from base region **2005** to emitter region **2006**) when emitter region **2006** is reversed biased or zero biased relative to base region **2005**. This current affects the cut-off mode operation of NPN transistor **2000**. Depending on whether or not emitter region **2006** of NPN transistor **2000** is in a forced depleted condition, determines base-to-emitter voltage V_{BE} is in a range that maintains emitter region **2006** fully depleted. FIG. **26** shows an example of the IV characteristics of NPN transistor **2000** when the emitter is forced depleted. The dashed line shows the IV characteristics of a conventional NPN transistor.

[0172] According to another embodiment of the present invention, four or more regions in different combinations of fully depleted or un-depleted (i.e., conventional) semiconductor regions may also be used to form NBDs. Further, whether or not a center semiconductor region may be fully depleted between two fully depleted adjacent semiconductor regions results in different NBDs. Therefore, all variations in an NBD with respect to the semiconductor material types, the numbers of fully depleted regions (whether or not in a forced-depletion condition), the numbers of un-depleted regions, the alignment or orientation of the semiconductor regions, the different doping concentrations are within the scope of the present invention. The forced and non-forced depletion conditions of the present invention can be applied to any device having one or more semiconductor regions that is not fully depleted to modify the behavior for such a device. This may also result in new devices.

[0173] It is known in the art that there are no contact materials that create a true p-type ohmic contact. Instead a p-type Ohmic contact may be emulated using a p-type Schottky contact with a sufficiently thin depletion region. The thin depletion region allows tunneling, as it is created using a highly doped p-type material. Using a highly doped p-type material may be undesirable or may not provide a low enough resistance. Another embodiment of the present invention creates a p-type Ohmic contact using an NBD structure which includes a contact, a forced depleted n-type region adjacent to the contact and a p-type region adjacent n-type region opposite the contact. As explained above, the built-in potentials between the forced depleted n-type region and the contact and the p-type region are reduced after an increasing and decreasing forward bias cycle if the p-type region has another depletion region within its neutral region. The forced depleted n-type region is sufficiently thin to allow tunneling between the contact and the p-type region. This p-type ohmic NBD structure may reduce the resistance between a p-type region and a contact in some circumstances. In another embodiment of the present invention a contact, a forced depleted p-type region adjacent to contact and a n-type region adjacent to n-type region opposite contact forms a n-type ohmic NBD structure.

[0174] A fully depleted region may be created using a p-type or an n-type material adjacent to an intrinsic material. In another embodiment of the present invention, an NBD uses a forced depleted region created by a p-type or an n-type semiconductor region adjacent to at least one intrinsic semiconductor region. In another embodiment of the present invention a NBD uses a non-forced depleted region created by a p-type or an n-type semiconductor region adjacent to at least one intrinsic semiconductor region.

[0175] In an NBD, when a p-type region is fully depleted at zero applied bias voltage, no drift current flows in it. Therefore, a thermally generated current carrying species of a non-fully depleted region, normally associated in a conventional pn junction diode with a leakage current does not occur in a fully depleted region. This is because an electric field forces any such electrons to move from the fully depleted p-region to the non-fully depleted region and any such holes to move from the non-fully depleted region to the fully depleted p-region, so that the NBD is conductive at zero bias. In some NBDs, such as a Schottky diode, the contacts to the devices can act as a p-type or n-type region.

[0176] FIG. **8**(*f*) shows multiple NBD **600**s connected in series in order to generate a voltage from a current source, thus supplying power to a load, according to application of the present invention. Therefore, the output voltage of multiple NBDs connected in series to generate a desired output voltage that is multiple times of a single NBD output voltage. NBDs may be connected in parallel to prevent an input current that is greater than the saturation current of any of the serially connected NBDs. By varying the number of NBDs and the manner of connection, variations of desired output voltages or currents may be achieved.

[0177] According to one of the embodiment of present invention, NBD **300** has characteristics as following: (1) low reverse current threshold voltage, (2) rectification of small signals (**3**) rectification of high frequency signals (**4**) conductivity at reverse-bias with appreciable amount of current and (5) reverse output voltage when connected in series with a current source. In addition, in a reverse bias mode, the conducting current of NBD **300** is significantly greater than the leakage current of a conventional diode prior to breakdown. Further, as the built-in voltage raises the output voltage level, NBD **300** indirectly raises the output power. New types of circuits for network switching, digital computing, signaling and waveform shaping (such as clipping and clamping) using NBDs are thus possible. Special diodes using P-type and N-type materials, including Step-Recovery (SRD), PIN and Zener diode types, may be created by modifying the depletion widths which may be determined, for example, by the steps described above. By having multiple p-type and n-type regions of different doping concentrations, other diode characteristics such as the saturation current, leakage current and input/output resistance can be created accordingly.

[0178] According to one embodiment of the present invention, different characteristics of an NBD may be achieved using degenerate materials. Devices using degenerate materials typically exhibit tunneling and negative resistance characteristics within voltage ranges that are less then V_{th}. An NBD with different values of V_s can shift tunneling and negative resistance voltage ranges. FIG. **25**(*a*) shows the current-voltage (IV) characteristics of NBD **300** fabricated using degenerate materials for one value of voltage V_s which is not close to V_{th}. NBD **300** in this configuration shows a larger voltage range in which tunneling occurs and a smaller voltage range in which negative resistance voltage occurs, relative to a conventional pn junction diode utilizing the same degenerate materials. FIG. **25**(*b*) shows the current-voltage (IV) characteristics of NBD **300** utilizing degenerate materials for another value of V_s which is selected to be closer to the threshold voltage V_{th}. NBDs in this configuration have larger minimum forward currents and reduced negative resistance values than a conventional pn junction diode utilizing the same degenerate materials.

[0179] The above examples show that tunneling devices can be provided by NBDs, in accordance with the present invention. Such tunneling devices have desirable characteristics in voltage range, current range and resistance. In one embodiment of present invention, tunneling diodes with different peak voltage, peak currents, valley voltages, or valley currents are also possible. High frequency applications using NBD type tunnel diodes are possible. By varying and mixing different types of materials in NBD devices, such as using a combination of nondegenerate and degenerate materials, new devices or new features may be achieved for existing devices.

[0180] Furthermore, the device in accordance with the present teaching are essentially low voltage devices or devices which can operate with a high signal-to-noise ratio, which makes them well suited to uses as detectors in optical communication systems. Drawings and figures for the EM rectenna of the present invention are provided for explanations and do not represent the relationship of connecting parts in scale, size or position. For example, top views of antenna design shown NBDs and electron input/output channels exposing, actual implementations may include other considerations. The figures used for describing the rectenna embodiments in this invention show semiconductor regions disproportionately large and placed in relationship to antennae for explanatory purposes only. Adjustments on the rectenna system may be required to obtain higher packing density or efficiency. According to the present invention, a highly doped n-type material can act as a contact under some situations. Also, a highly doped p-type material can act as a contact under some situations.

[0181] A fully depleted region in a device at zero applied bias voltage achieves: (1) When a region is fully depleted at zero applied bias voltage, electrons at the contact/semiconductor junction move from fully depleted p-region to the n-region (positive particle (holes) at the contact/semiconductor junction move from fully depleted n-region to the p-region) as a result of the electric field created by the depletion region. In this case, the distance between the fully depleted p-region and external electrons at the contact/semiconductor junction (the distance between the fully depleted n-region and external positive particles (holes) at the contact/semiconductor junction) is zero. As a result, a reverse bias conducting current is achieved. (2) If a fully depleted p-region has external electrons at the contact/semiconductor junction (a fully depleted n-region has external positive particles (holes) at the contact/semiconductor junction), the reverse bias conductivity occurs without a threshold voltage. (3) The electron at the contact semiconductor junction move against the direction of the electric field created by the depletion region (the external positive particles (holes) at the contact semiconductor junction move in the same direction of the electrical field). For example, an NBD conducts at reverse bias without having a breakdown voltage, as in the case of a conventional diode. (4) An NBD partitions conventional PN junction depletion regions into two electric fields.

[0182] The present invention is applicable also to rectenna elements other than dipole rectenna elements. Also, the NBDs of the present invention can be used with practically any antenna types and size to achieve an EM wave to DC power conversion. For an antenna type in which points of maximum voltages or currents may be determined, and for which a gap may be positioned without affecting the operating EM wave frequency response, a gap with an associated NBD may be placed at one or more of such maximum current points. Otherwise, for such an antenna type, a non-gap or gap-less rectenna element may be used by finding maximum voltage points and, at each maximum voltage point along the antenna, place a pair of NBDs to form an input terminal and an output terminal, such as shown in FIGS. **20**(*a*) and **20**(*b*).

[0183] Using the parallel and series connection discussed above for connecting dipole rectennae elements into rectenna arrays, a device can be designed to output any voltage with any antenna type. Further, the rectenna elements on each device may be different, so that a single device may be made to capture various frequencies within a large spectrum of EM waves. Also, different portions of a single device may include rectenna elements of different antenna types and these different portions may be used to perform different functions. The present invention is not limited to a dipole rectenna design, nor to the full wave rectifying rectenna described above. In accordance with the embodiments of the invention, each rectenna element can be of any size, shape or type. In addition, a rectenna array can include more than one type of rectenna elements. For example, in an RFID application, a portion of a rectenna array may be sensitive to one frequency and is used to capture the EM wave to power the RFID circuit, while another portion of the rectenna array may be used for RF transmission and reception. Such an arrangement reduces the required number of parts and creates a more compact design. The single plane construction is not limited to contiguous dipoles but is also applicable to the more usual case of separate dipoles. Although the above configurations mentioned only planar arrays, the present invention is applicable also to non-planar arrays. The invention can also be carried out using discrete parts. Because an NBD of the present invention can rectify very high frequency signals, an EM rectenna of the present invention can be used to detect and rectify very high frequency EM waves efficiently. Thus, detection and power conversion from new frequencies in the EM spectrum can now be achieved where previously were impractical or impossible. This includes generating DC power from the IR and visible light spectra (e.g., solar energy) and fast response photo-sensors for optical sensing and optical networks. The present invention ability to absorb IR frequencies at high efficiencies may be used in such applications as heat shields and cooling devices.

[0184] One of the main obstacles preventing the proliferation of solar energy conversion systems is efficiency. The main issue with efficiency is mostly on the rectifiers and the ways that the rectifiers are connected to the antenna. The embodiments presented in the EM rectenna of the present invention improve the efficiency of converting electromagnetic (EM) waves to DC electricity over the prior art by providing the improvements in: (1) full wave rectification for a broader input signal frequency range (e.g., frequencies at or above infra-red), (2) solving the voltage drop problems in rectifiers[3], (3) providing an output voltage level for higher efficiency by utilizing special rectifiers that output a voltage in response to a small signal, (4) full wave rectification with fewer rectifiers, and (5) providing two sources of input currents, one from the received EM wave and the other one from the electron input channels.

[3] A rectifier (typically a diode) in the prior art requires a bias voltage drop across it before it conducts current. A voltage drop creates power loss, especially for low power signals. The voltage drop issue is important in solar engines, since the voltage drop reduces the voltage supplied to the load.

[0185] While only dipole antennae are used to illustrate the rectennae of the present invention, the methods discussed above may be used to incorporate other antenna types and sizes into the rectenna of the present invention.

[0186] The detailed description above is provided to illustrate the specific embodiments above and is not intended to be limiting. Numerous modifications and variations within the scope of the present invention are possible. The present invention is set forth in the following claims.

We claim:

1. A semiconductor device, comprising a semiconductor region that is fully depleted at zero bias voltage across the semiconductor device.

2. A semiconductor device as in claim **1**, further comprising a contact adjacent the first semiconductor region.

3. A semiconductor device as in claim **1**, further comprising a second semiconductor region forming a pn junction with the first semiconductor region.

4. A semiconductor device as in claim **3**, wherein the semiconductor device conducts a current substantially linearly, when a reverse bias voltage is imposed across the pn-junction.

5. A semiconductor device as in claim **1**, wherein the first semiconductor region is a forced depletion region.

6. A semiconductor device as in claim **1**, wherein the first semiconductor region is a non-forced depletion region.

7. A semiconductor device as in claim **5**, wherein the Fermi level of the semiconductor region is closer to the intrinsic Fermi level of the semiconductor region than the Fermi level of the semiconductor device as zero bias voltage.

8. A semiconductor device as in claim **5**, further comprising a voltage difference equal to voltage difference associated to energy difference between the fermi level of the semiconductor region and the fermi level of the semiconductor device.

9. A method for creating a natural breakdown device, comprising:

providing a semiconductor device with a junction formed by a first semiconductor region and a region of a predetermined material, wherein the first semiconductor region has a width greater than its depletion width;

adjusting a parameter of the region of the predetermined material such that the width of the first semiconductor is equal to or less than the expected depletion width of the first semiconductor region.

10. A method as in claim **9**, wherein the predetermined material comprises a second semiconductor region and the parameter adjusted comprises a dopant concentration.

11. A method as in claim **9**, wherein the predetermined material comprises a conductor material forming a contact and the parameter adjusted comprises a work function of the conductor material.

12. A method as in claim **9**, wherein the parameter adjusted is a dimension of the region of the predetermined material relative the width the dimension of the semiconductor region.

13. A rectenna, comprising:

a conductive portion including a first point and a second point separated by a predetermined distance, such that when the conductive portion is irradiated by an electromagnetic wave, the first point and the second point constitute points of maximum voltage; and

a semiconductor diode adjacent said first point comprising a p-region in contact with the conductive portion and an n-region in contact with the p-region.

14. A rectenna as in claim **13**, further comprising a second semiconductor diode adjacent the second point comprising a p-region in contact with the conductive portion and an n-region in contact with the p-region.

15. A rectenna as in claim **13**, wherein the rectenna is one of a plurality of antennae forming an rectenna array by connecting the p-regions of the second semiconductor diodes of the rectennae to form an input channel and connecting the n-regions of the first semiconductor diodes of the rectennae to form an output channel.

16. A rectenna as in claim **15**, wherein the rectennae in the rectenna array perform two or more functions.

17. A rectenna as in claim **13**, wherein the p-region and the n-region have respectively a first doping concentration and a second doping concentration and wherein the p-region is fully depleted at a zero applied voltage across the p-region and the n-region.

18. A rectenna, comprising:

a first conductive portion;

a second conductive portion separated from the first conductive portion by a gap that is substantially smaller than the combined lengths of the first conductive portion and the second conductive portion; and

a semiconductor device having a p-region and an n-region, the p-region being in contact with the first conductive portion at the gap.

19. A rectenna as in claim **18**, wherein the p-region of the semiconductor device contacts the second conductive portion at the gap.

20. A rectenna as in claim **18**, further comprising a second semiconductor device having a p-region and an n-region, the p-region being in contact with the second portion at the gap wherein the first and second semiconductor device is isolated from each other.

21. A rectenna as in claim **18**, further comprising an n-region in contact with an end portion of the first conductive portion away from the gap.

22. A rectenna as in claim **18**, wherein the p-region and the n-region of the semiconductor device have respectively a first doping concentration and a second doping concentration and wherein the p-region is fully depleted at zero bias voltage across the p-region and the n-region.

23. A rectenna as in claim **18**, further comprising an n-region in contact with one end of the second conductive portion away from the gap.

24. A rectenna as in claim **18**, wherein the rectenna is one of a plurality of rectennae in a rectenna array.

25. A rectenna as in claim **24**, wherein the rectenna array is formed by connecting the n-regions of the semiconductor devices of the rectennae to form an output channel to form an output channel and by connecting the n-regions of those ends of the first conductive portions and the second conductive portions away from the gap to form an input channel.

26. A rectenna as in claim **25**, wherein the rectennae in the rectenna array perform two or more functions.

27. A method to modify the Fermi energy level within a semiconductor region comprising,

providing a semiconductor device with a first semiconductor region of a first conductivity type and at first Fermi level, the first semiconductor region being forced depleted at zero biasing across the semiconductor device;

adjusting the first semiconductor region to a second Fermi level at thermal equilibrium, the second Fermi level being closer to the first semiconductor region intrinsic semiconductor Fermi level than the first Fermi level; providing a sub-threshold bias voltage across the semiconductor device;

28. A method as in claim **27**, wherein a voltage difference in a neutral region adjacent the first semiconductor region is created before the Fermi level of the first semiconductor region moves toward the second Fermi level

29. A method as in claim **27**, wherein the Fermi level of first semiconductor region is adjusted toward the first Fermi level before a voltage difference is created in a neutral region adjacent to the first semiconductor region.

30. A natural breakdown diode, comprising:

a first semiconductor region of a first conductivity type having a first doping concentration;

a second semiconductor region of a second conductivity type opposite first conductivity type having a second doping concentration; and

an ohmic contact adjacent the first semiconductor region; wherein the first semiconductor region is fully depleted at zero bias voltage across the first semiconductor region and the second semiconductor region.

31. A natural breakdown diode as in claim **30**, further comprises a third semiconductor region of first semiconductor type between the first semiconductor region and the ohmic contact, and wherein the first semiconductor region and the third semiconductor region are fully depleted at a zero bias voltage across the first semiconductor region, second semiconductor region and third semiconductor region.

32. A natural breakdown diode as in claim **31**, wherein the natural breakdown diode is conducting when a negative bias voltage is imposed across the first semiconductor region and second semiconductor region.

33. A natural breakdown diode as in claim **30**, wherein the natural breakdown diode provides a substantially constant output when a bias voltage between zero volts and a predetermined voltage V_s is imposed across the first semiconductor region and second semiconductor region.

34. A natural breakdown diode as in claim **30**, further comprising a third semiconductor region of second semiconductor type between the second semiconductor region and first semiconductor region.

35. A natural breakdown diode as in claim **30**, wherein the n-region is fully depleted at zero bias voltage across the p-region and the n-region.

36. A method for providing a natural breakdown diode, comprising:

(1) determining the doping concentrations of a p-region and an n-region of a conventional pn junction diode;

(2) selecting a forward-bias voltage V_s less than the conventional pn junction diode threshold voltage V_{th} and which is less than a predetermined maximum bias voltage for the diode; and

(3) calculating the depletion width w_p of the conventional pn junction diode when a bias voltage of V_s is imposed across the p-region and the n-region of the conventional pn junction diode;

(4) providing w_p as the width of a p-region the natural breakdown diode.

37. A method as in claim **36**, further comprising calculating the electric field across a pn junction in the natural breakdown diode and adjusting the doping concentrations of the p-region and an n-region of the natural breakdown diode such that natural breakdown diode is conducting at zero bias voltage.

38. A method for constructing a rectenna, comprising:

providing a conductive portion including a first point and a second point separated by a predetermined distance, such that when the conductive portion is irradiated by an electromagnetic wave, the first point and the second point constitute points of maximum voltage; and

providing a semiconductor diode adjacent said first point comprising a p-region in contact with the conductive portion and an n-region in contact with the p-region.

39. A method as in claim **38**, further comprising providing a second semiconductor diode adjacent the first point comprising a first n-region in contact with the conductive portion and a p-region in contact with the n-region.

40. A method as in claim **38**, further comprising providing a second semiconductor diode adjacent the second point comprising a p-region in contact with the conductive portion and an n-region in contact with the p-region.

41. A method as in claim **38**, further comprising:

providing a plurality of rectennae arranged in a rectenna array;

connecting the p-regions of the second semiconductor diodes of the rectennae to form an input channel; and

connecting the n-regions of the first semiconductor diodes of the rectennae to form an output channel.

42. A method as in claim **41**, further comprising providing two or more functions to be performed by the rectennae in the rectenna array.

43. A method as in claim **42**, further comprising providing the p-region and the n-region to have respectively a first doping concentration and a second doping concentration and providing that the p-region is fully depleted at a zero bias voltage across the p-region and the n-region.

44. A method as in claim **41**, further comprising providing a plurality of the rectenna arrays by connecting the input channels of the rectenna arrays together; and connecting the output channels of rectenna arrays together.

45. A method as in claim **36**, further comprising:

providing an increasing bias voltage across the natural breakdown diode;

applying a decreasing bias voltage across the natural breakdown diode, such that a charge builds up in a neutral region of the n-region.

46. A method as in claim **27**, wherein a depletion region associated with the first semiconductor region has the same width during the application of the decreasing bias voltage.

47. A method for providing a rectenna, comprising:

providing a first conductive portion;

providing a second conductive portion separated from the first conductive portion by a gap that is substantially smaller than the combined lengths of the first conductive portion and the second conductive portion; and

providing a semiconductor device having a p-region and an n-region, the p-region being in contact with both the first conductive portion and the second conductive portion at the gap.

48. A method as in claim **47**, wherein the p-region of the semiconductor device contacts the second conductive portion at the gap.

49. A method as in claim **47**, further comprising a second semiconductor device having a p-region and an n-region, the p-region being in contact with the second portion at the gap.

50. A method as in claim **49**, wherein the first and second semiconductor device is isolated from each other.

51. A method as in claim **50**, further comprising providing an n-region in contact with an end portion of the fist conductive portion away from the gap.

52. A method as in claim **51**, further comprising providing the p-region and the n-region of the semiconductor device to have respectively a first doping concentration and a second doping concentration and providing that the p-region is fully depleted at zero bias voltage across the p-region and the n-region.

53. A method as in claim **47**, further comprising an n-region in contact with one end of the first conductive portion away from the gap.

54. A method as in claim **47**, further comprising providing the rectenna to be one of a plurality of rectennae in a rectenna array.

55. A method as in claim **51**, wherein providing the rectenna to be one of a plurality of rectennae in a rectenna array comprises:

providing the plurality of rectennae;

connecting the n-regions of the semiconductor devices of the rectennae to form an output channel to form an output channel; and

connecting the n-regions of those ends of the first conductive portions and the second conductive portions away from the gap to form an input channel.

56. A method in claim **55**, wherein the rectenna is one of a plurality of rectennae arranged in a plurality of rectenna arrays, the method further comprising:

providing a plurality of the rectennae arrays;

connecting the input channels of the rectenna arrays together; and

connecting the output channels of rectenna arrays together.

57. A method as in claim **56**, wherein the rectenna array is one of a plurality of rectenna arrays, the method further comprising:

providing the plurality of rectenna arrays;

connecting the p-regions of the second semiconductor diodes of the rectennae to form an input channel; and

connecting the n-regions of the first semiconductor diodes of the rectennae to form an output channel.

58. A method as in claim **57**, wherein the rectennae in the rectenna array perform two or more functions.

59. A method as in claim **57**, wherein the first conductive portion and the second conductive portion are provided a predetermined combined length which is substantially half of an odd multiple of a wavelength of the electromagnetic wave.

60. A method for providing a natural breakdown diode, comprising:

providing a first semiconductor region of a first conductivity type having a first doping concentration and providing a second semiconductor region of a second conductivity type opposite first conductivity having a second doping concentration;

providing a width for the first semiconductor region that is less than or equal to a first semiconductor region depletion width of a conventional diode having a first semiconductor region of the first doping concentration and a second doping concentration; and

providing an ohmic contact adjacent the first semiconductor region.

61. A method as in claim **60**, further comprises providing a third semiconductor region of same conductivity type as first conductivity type between the first semiconductor region and the ohmic contact having a third doping concentration, wherein the first semiconductor region and the third semiconductor region are fully depleted at zero bias voltage across first semiconductor region, the second semiconductor region and the third semiconductor region.

62. A method as in claim **60**, further comprising providing the diode to operate at break down mode when a zero bias voltage is imposed across the first semiconductor region and the second semiconductor region.

63. A method as in claim **60**, further comprising providing the diode a constant voltage output when a bias voltage between zero volts and a predetermined voltage V_s is imposed across the p-region and the n-region.

64. A method as in claim **60**, further comprising providing a third semiconductor region of same conductivity type as second conductivity type between the second semiconductor region and the first semiconductor region.

65. A method as in claim **60**, further providing the second semiconductor region to be fully depleted at zero bias voltage across the first semiconductor region and the second semiconductor region.

66. A method for collecting electromagnetic radiation power, comprising:

providing a plurality of antennae elements forming an array having an input channel and an output channel, wherein each antenna element comprising:

a conductive portion including a first point and a second point separated by a predetermined distance, such that when the conductive portion is irradiated by an electromagnetic wave, the first point and the second point constitute points of maximum voltage; and

a semiconductor diode adjacent said first point comprising a p-region in contact with the conductive portion and an n-region in contact with the p-region; and

providing a power storage device for receiving a current from the antenna array, the power storage device being connected across the input channel and the output channel.

67. A method as in claim **66**, wherein the antenna element further comprises a second semiconductor diode adjacent the first point comprising a first n-region in contact with the conductive portion and a p-region in contact with the n-region.

68. A method as in claim **66**, wherein the p-regions of the second semiconductor diodes of the antenna array to form the input channel and connecting the n-regions of the first semiconductor diodes of the antenna array to form the output channel.

69. A method as in claim **66**, wherein the antenna element further comprises a second semiconductor diode adjacent the second point comprising a p-region in contact with the conductive portion and an n-region in contact with the p-region.

70. An antenna element, comprising:

an input terminal;

an output terminal;

a first conductor and a second conductor separated by a gap each conductor having a first end and a second end, respectively, wherein the second ends of each conductor is located at the gap, the first end of each conductor is connected to the input terminal, and the total lengths of the first conductor, the second conductor and the gap equal to a predetermined value related to the wavelength an electromagnetic radiation to be received by the antenna element; and

a first rectifier coupled between the second end of the first conductor and the output terminal.

71. An antenna element as in claim **70**, wherein a second rectifier is coupled between the second end of the second conductor and the output terminal.

72. An antenna element as in claim **70** wherein, when an electromagnetic radiation is incident to the antenna element, a first electrical current is induced in the antenna element due to a voltage difference along each conductor, and a second electrical current is induced in the antenna element by a magnetic field of the electromagnetic radiation.

73. An antenna element as in claim **70**, wherein the rectifier is conducting at a zero bias voltage

74. An antenna array comprising a plurality of antenna elements interconnected by semiconductor devices.

75. A rectifier, comprising:

a conductor having a first end and a second end; and

a semiconductor device connected to the first end of the conductor, wherein the semiconductor device including a semiconductor region that is fully depleted at zero bias voltage.

76. A rectifier as in claim **75**, further comprising a second semiconductor device, connected to the conductor that includes a semiconductor region that is fully depleted at zero bias voltage.

77. A rectifier as in claim **75**, further including a second conductor separated from the first conductor by a gap.

78. In a semiconductor device, a method for transferring a potential from a first built-in potential to a second build-in potential, comprising:

providing a first forced fully-depleted semiconductor region of a first conductivity type;

providing a second semiconductor region of a second conductivity type different from the first conductivity type, the second conductor region being adjacent the first semiconductor region and having a first built-in potential;

providing s second built-in potential adjacent the second semiconductor region opposite first built-in potential;

providing an increasing forward bias relative to first semiconductor region; and

providing a decreasing forward bias relative to first semiconductor region, such that first built-in potential is decreased and second built-in potential is increased.

79. A method as in claim **78**, wherein the threshold voltage of the semiconductor device is less than the threshold voltage of a conventional pn junction.

80. A method for modifying a built-in potential of a semiconductor device, comprising:

creating in a semiconductor substrate a pn-junction of a predetermined built-in potential; and

providing in the semiconductor substrate at a predetermined distance from the pn-junction a semiconductor region that is fully depleted when the semiconductor device is at zero bias voltage.

81. A method as in claim **80**, wherein the fully depleted semiconductor region is provided by an ohmic contact to a suitably doped semiconductor region.

82. A method as in claim **80**, wherein the fully depleted semiconductor region is provided by a Schottky contact to a suitably doped semiconductor region.

83. A method for signal power storage in a semiconductor, comprising:

providing a semiconductor device including a semiconductor region that is fully depleted at zero bias voltage; and

applying a sub-threshold bias voltage across the semiconductor region.

84. An Ohmic contact within a semiconductor device comprising:

a first semiconductor region of a first conductivity type;

a second semiconductor region of a second conductivity type opposite first conductivity type;

a contact adjacent to the first semiconductor region, the second semiconductor region adjacent to the first semiconductor region opposite a contact, the first semiconductor region being sufficiently thin to create an ohmic coupling between the second semiconductor region and the contact.

85. A method for providing an Ohmic contact within a semiconductor device, comprising:

providing a first semiconductor region of a first conductivity type; and

providing a second semiconductor region of a second conductivity type opposite the first conductivity type adjacent to the first semiconductor region; and

providing a contact adjacent to first semiconductor region opposite second semiconductor region wherein the first semiconductor region is sufficiently thin to create an ohmic coupling between the second semiconductor region and the contact.

86. A method to fully rectify an input signal with a single semiconductor device, comprising,

providing a first semiconductor region of a first conductivity type;

providing a second semiconductor region of a second conductivity type opposite first conductivity type adjacent to the first semiconductor region;

providing an ohmic contact adjacent to first semiconductor region opposite the second semiconductor region;

providing the first semiconductor region is forced depleted at zero bias voltage across the contact, the first semiconductor region and the second semiconductor region; and

providing the input signal.

(57) **ABSTRACT**

A device for receiving wireless power includes a point of reception, wherein the point of reception is positionable in at least a first position and a second position. A method for receiving wireless power. The method includes the steps of positioning a point of reception in contact with a housing to a first position. There is the step of receiving wireless power at the point of reception and providing it to a power harvester in the housing. There is the step of converting the wireless power to usable DC with the power harvester. There is the step of providing the usable DC to core components in the housing. There is the step of using the DC by the core components. There is the step of repositioning the point of reception to a second position. There is the step of receiving wireless power at the point of reception at the second position and providing it to the power harvester. There is the step of converting the wireless power received by the point of reception in the second position to usable DC with the power harvester. There is the step of providing the usable DC to the core components in the housing. There is the step of using the DC by the core components.

POWERING CELL PHONES AND SIMILAR DEVICES USING RF ENERGY HARVESTING

FIELD OF THE INVENTION

[0001] The present invention is related to the wireless powering of devices. More specifically, the present invention is related to the wireless powering of devices, namely cell phones and the like, with a power harvester.

BACKGROUND OF THE INVENTION

[0002] As processor capabilities have expanded and power requirements have decreased there has been an ongoing explosion of devices that operate completely independent of wires or power cords. These "untethered" devices range from cell phones, and wireless keyboards to building sensors and active RFID tags.

[0003] Engineers and designers of these untethered devices continue to have to deal with the limitations of portable power sources, primarily batteries as the key design parameter. While performance of processors and portable devices have been doubling every 18-24 months driven by Moore's law, battery technology in terms of capacity has only been growing at measly 6% per year. Even with power conscious designs and the latest in battery technology, many devices do not provide the lifetime cost and maintenance requirements for applications that require a large number of untethered devices such as logistics, and building automation. Today's devices that need two-way communication require scheduled maintenance every three to 18 months to replace or recharge the device's power source (typically a battery). One-way devices simply broadcasting their status (one-way) such as automated utility meter readers have a better battery life, typically requiring replacement within 10 years. For both device types, scheduled power-source maintenance is costly and disruptive to the entire system that a device is intended to monitor and/or control. Unscheduled maintenance trips are even more costly and disruptive. On a macro level, the relatively high cost associated with the internal battery also reduces the practical, or economically viable, number of devices that can be deployed.

[0004] The ideal solution to the power problem for untethered devices is a device or system that can collect and harness sufficient energy from the external environment. The harnessed energy would then either directly power an untethered device or augment a battery or other storage component. Directly powering an untethered device enables the device to be constructed without the need for a battery. Augmenting a storage component could be along two lines: 1) increasing the overall life of the device or 2) by providing more power to the device to increase the functionality of the device. The other parameters for an ideal solution is that the harnessing device could be used in a wide range of environments including harsh and sealed environments (e.g. nuclear reactors), would be inexpensive to produce, would be safe for humans, and would have a minimal effect on the basic size, weight and other physical characteristics of the untethered device.

BRIEF SUMMARY OF THE INVENTION

[0005] The present invention pertains to a device for receiving wireless power. The device comprises a point of reception, wherein the point of reception is positionable in at least a first position and a second position.

[0006] The present invention pertains to a method for receiving wireless power. The method comprises the steps of positioning a point of reception in contact with a housing to a first position. There is the step of receiving wireless power at the point of reception and providing it to a power harvester in the housing. There is the step of converting the wireless power to usable DC with the power harvester. There is the step of providing the usable DC to the core components in the housing. There is the step of using the DC by the core components. There is the step of repositioning the point of reception to a second position. There is the step of receiving wireless power at the point of reception at the second position and providing it to the power harvester. There is the step of converting the wireless power received by the point of reception in the second position to usable DC with the power harvester. There is the step of providing the usable DC to the core component in the housing. There is the step of using the DC by the core components.

[0007] The present invention pertains to an apparatus for an application. The apparatus comprises a core device preferably having an integrated circuit for the application. The apparatus comprises a power harvester connected to the core device to power the core device.

[0008] The present invention pertains to an apparatus for an application. The apparatus comprises a core device having an integrated circuit for the application. The apparatus comprises means for receiving energy wirelessly and providing power from the energy to the core device to power the integrated circuit of the core device. The receiving means is connected to the core device.

[0009] The present invention pertains to a method for an application. The method comprises the steps of converting RF energy into usable energy. There is the step of preferably powering an integrated circuit of the core device with the usable energy.

[0010] This invention pertains to a technique that uses radio frequency (RF) energy as a source of energy to directly power or augment a power storage component in an untethered device. The present invention meets the requirements described in the previous "Background of the Invention" section.

[0011] Traditional RF receiving devices have focused on maximizing selectivity of the frequency to isolate and to be coherent without interference from other sources. In contrast, while this methodology operates at a specific frequency or range of frequencies, the device accepts any interference to supplement the output power of the device. Also, the research related to power harvesting that uses RF energy as a source has primarily focused on devices in close proximity of the source. In most cases, prior research assumed a dedicated or directed source of RF to power the device.

[0012] It is an object of this invention to provide a method and apparatus to

[0013] 1. remotely energize an untethered device without using direct wiring

[0014] 2. power or augment the life of the power storage component so it matches the life of the device and, ultimately, powers the off-grid device with or without the use of batteries

[0015] 3. allow untethered devices to be virtually maintenance free

[0016] 4. provide augmentation for other energy harvesting technologies (solar, piezoelectric, etc.)

[0017] 5. provide backup power to tethered devices

[0018] It is a further object of this invention to directly power or augment a power storage component in an untethered device in conjunction with other power harvesting technologies and storage elements.

[0019] With this method and apparatus a device's power storage components do not require replacement, thus enabling the device to be permanently placed off-grid, where it may be physically impractical, costly, or dangerous (due to a harsh environment) to provide maintenance.

[0020] For devices on-grid (tethered) or with reliable power sources, RF power harvesting can be used as a backup in case the primary power source is lost.

BRIEF DESCRIPTION OF THE SEVERAL VIEWS OF THE DRAWING

[0021] In the accompanying drawings, the preferred embodiment of the invention and preferred methods of practicing the invention are illustrated in which:

[0022] FIG. **1** is a block diagram of the RF Power Harvesting block used to directly supply power to the Core Device Components.

[0023] FIG. **2** is a block diagram of the RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit.

DETAILED DESCRIPTION OF THE INVENTION

[0124] A complete understanding of the invention will be obtained from the following description when taken in connection with the accompanying drawing figures wherein like reference characters identify like parts throughout.

[0125] There is shown an apparatus **10** for an application. The apparatus **10** comprises a core device **22** preferably having an integrated circuit for the application. The apparatus **10** comprises a power harvester **20** connected to the core device **22** to power the core device **22**.

[0126] The apparatus **10** preferably includes an alternative power source **24** connected to the core device **22** to power the core device **22** in conjunction with the power harvester **20**. Preferably, the apparatus **10** includes a power regulator **26** and/or power storage circuit **28** connected to the power harvester **20**. The apparatus **10** preferably includes a power storage charger **30** connected to the power harvester **20**. Preferably, the apparatus **10** includes a power storage connected to the power harvester **20**.

[0127] Preferably, the core device **22** includes a memory connected to the integrated circuit and to the power harvester **20** to power memory.

[0128] The core device **22** can include a sensor **32**, as shown in FIG. **89**. The sensor **32** can include a proximity sensor, an intrusion sensor, an environmental sensor, a chemical sensor, a biological sensor, a sensor in contact with an automobile, an occupancy sensor, a motion sensor, a position sensor, a metal detector, or a sensor **32** in contact with an aircraft. The sensor **32** can include an alarm connected with the power harvester **20** to power the alarm, a display connected with the power harvester **20** to power the display, a sensor **32** disposed in a building, an industrial automation sensor, a sensor **32** in contact with an elevator, a temperature sensor, a fire sensor, an accelerometer, or a level sensor.

[0129] The sensor **32** can include a gas level sensor, a fluid level sensor, a light level sensor, a flow sensor, or a gas flow sensor, a fluid flow sensor, a light flow sensor, or a plasma flow sensor.

[0130] The sensor **32** can include a pressure sensor, a gas pressure sensor or a fluid pressure sensor, a fluid pressure sensor, a light sensor, an infrared light sensor, an ultraviolet light sensor, an x-ray sensor, a cosmic ray sensor, a visible light sensor, or a gamma ray sensor, a stress sensor, a strain sensor, a depth sensor, or an electrical characteristic sensor.

[0131] The sensor **32** includes a voltage sensor, a current sensor, a viscosity sensor, an acoustical sensor, a sound sensor, a listening sensor, a thickness sensor, a density sensor, a surface quality sensor, a volume sensor, a physical sensor, a mass sensor, a weight sensor, a conductivity sensor, a distance sensor, an orientation sensor, or a vibration sensor.

[0132] The sensor **32** can include a radioactivity sensor, a field strength sensor, an electric field sensor or a magnetic field sensor, a smoke detector, a carbon monoxide detector, a radon detector, an air quality sensor, a humidity sensor, a glass breakage sensor, or a break beam detector. The sensor can include a thermal energy sensor, an electromagnetic sensor, a mechanical sensor, an optical sensor, a radiation sensor, a sensor in contact with a vehicle, or a water craft.

[0133] The present invention pertains to an apparatus **10** for an application. The apparatus **10** comprises a core device **22** having an integrated circuit for the application. The apparatus **10** comprises means for receiving energy wirelessly and providing power from the energy to the core device **22** to power the integrated circuit of the core device **22**. The receiving means is connected to the core device **22**. Preferably, the core device **22** includes means for sensing.

[0134] Alternatively, the core device **22** can include a computer peripheral **34**, as shown in FIG. **90**. The computer peripheral **34** can include a handheld game, a gaming system, a game controller, a controller, a keyboard, a mouse, a computer terminal, computer storage, or computer equipment.

[0135] The present invention pertains to a method for an application. The method comprises the steps of converting rf energy into usable energy. There is the step of preferably powering an integrated circuit of the core device **22** with the usable energy.

[0136] Preferably, there is the step of regulating the usable energy provided to the core device **22**. There is preferably the step of storing the usable energy. Preferably, there is the step of providing power to the core device **22** from an alternative power source **24** in conjunction with the usable energy.

[0137] The present invention can be implemented in numerous ways. Most of these ways are depicted in FIGS. **1-88**. These figures contain multiple blocks that are configured in multiple ways. In the figures, an arrow represents the flow of power unless otherwise stated. Single-headed (one-way) arrows represent that the power is flowing from one block to another. The single-headed arrow may represent multiple wires that provide power from one block to multiple parts in the other block. Two-headed (two-way) arrows represent a single wire that can have power flow in either direction or multiple wires each having power flow in a single direction. As an example, a two-headed arrow between the RF Power Harvesting block and the Power Regulation and/or Power Storage circuit **28** block can represent a single wire that allows harvested power to flow into a storage device such as a capacitor. The same block diagram can also represent two wires between the two blocks with the first wire allowing harvested power to flow into a voltage regulator **26**. The second wire can allow the regulated voltage to feedback to the RF Power Harvesting block to provide power to internal components such as transistors to increase the performance of the RF Power Harvesting block. Each block is described in detail below. Each block represents the functionality described below associated with it. For instance, the RF power harvesting block describes a power harvester **20**, and the power regulation block describes a power regulator **26**.

[0138] RF Power Harvesting Block

[0139] The RF Power Harvesting Block is used to convert the energy captured by the antenna into usable power such as DC voltage. This block may include antenna matching, rectifying circuitry, voltage transforming circuitry, and/or other performance optimizing circuitry. The rectifying circuitry may include a diode(s), a transistor(s), or some other rectifying device or combination. Examples of the rectifying circuitry include but are not limited to half-wave, full-wave, and voltage doubling circuits. The RF power harvesting block is connected to an antenna that may or may not be used as the communications antenna for the core device **22** components. The output of the RF Power Harvesting Block is a DC voltage or current. The RF Power Harvesting Block may accept feedback (or input) from other circuitry or blocks, which may be used to control the harvesting circuitry to improve the performance or vary the output. This feedback may include but is not limited to a DC voltage or a clock from the Core device **22** Components. U.S. Pat. No. 6,615,074 (FIGS. 8, 9, 12a, 12b, 13, 14), incorporated by reference, herein, shows numerous examples of RF power harvesting circuits that can be used to implement the block and function described.

[0140] Power Regulation and/or Power Storage Circuit **28** Block

[0141] It may be necessary to regulate the converted power (hold the power at a constant level) for specific devices. The devices that would need this block require a fairly constant voltage or current. Deviations from the required values may cause the device to not perform within its specifications. The regulation can be implemented in many different ways. The block can be as simple as using a Zener diode, or as complicated as using an integrated circuit such as a linear voltage regulator **26** or switching regulator **26** to hold the voltage at a constant level. Certain devices have a more tolerable power requirement. For these devices, the regulation stage may be excluded. This block may also include, with or without the regulation, a storage device such as a capacitor, a battery, or some other device able to store charge. The output from the Power Regulation and/or Power Storage circuit **28** Block may be used as feedback to other blocks within the Device's Power System or to the Alternative power source **24** if they require a regulated supply voltage or stored power. U.S. Pat. No. 6,894,467 (FIGS. 1, 3), Linear Voltage Regulator, incorporated by reference, herein, is an example of a practical application of implementing the regulation described in the block. U.S. Pat. No. 6,297,618 (FIGS. 1-4), Power storage device and method of measuring voltage of storage battery, incorporated by reference, herein, is an example of a practical application of implementing the storage described in the block.

[0142] Power Storage Charger **30** Block

[0143] The Power Storage Charger **30** Block may be needed if the storage component requires a special charging mechanism such as pulse charging or trickle charging. This block controls how the captured and converted power is supplied to the storage device. U.S. Pat. No. 6,836,095 (FIGS. 1-3), Battery Charging Method and Apparatus, incorporated by reference herein, is an example of a practical application of implementing the special charging mechanism described in the block.

[0144] Power Storage Block

[0145] If a device has intermittent power requirements, it may be necessary to store the captured power for use at a later time. The power can be stored in the Power Storage block, which could include a battery, a capacitor, and/or another type of power storage component. Storage components include but are not limited to batteries (rechargeable and non-rechargeable), capacitors, inductors, fuel cells, and other storage elements. The output from the Power Storage Block may be used as feedback to other blocks within the Device's Power System or to the Alternative power source **24** if they require a dedicated and predictable supply voltage. U.S. Pat. No. 6,297,618 (FIGS. 1-4), Power Storage Device and Method of Measuring Voltage of Storage Battery, incorporated by reference herein, is an example of a practical application of implementing the storage described in the block. U.S. Pat. No. 6,835,501, Alkaline Rechargeable Battery, incorporated by reference herein, is also an example of a practical application of implementing the storage described in the block.

[0146] Core Device **22** Components Block

[0147] The Core Device **22** Components Block is the device that is receiving power from the system. This block may be but is not limited to the devices listed in the subsequent pages of this document. It may be advantageous for the Core Device **22** Components to communicate with any of the blocks that are supplying power to it. This communication can include but is not limited to a feedback control signal such as a clock or an ON/OFF command. As an example, the device may want to turn off the Alternative Power Sources **24** block if it is receiving sufficient power from the RF Power Harvesting block.

[0148] Alternative Power Sources **24** Block

[0149] RF energy harvesting also has the ability to be augmented by other types of power harvesting, storage components, or dedicated sources (e.g. power line). The Alternative Power Sources **24** Block shows how this type of system could be implemented. The augmenting power harvesting technologies include but are not limited to solar, light (visible and non-visible), piezoelectric, vibration, acoustic, thermal, microgenerators, wind, and other environmental elements. This block can work independently or have communication with other blocks. U.S. Pat. No. 6,784,358, Solar Cell Structure Utilizing an Amorphous Silicon Discrete By-Pass Diode, incorporated by reference herein, is an example of a practical application of implementing an alternative power source **24** described by the block. U.S. Pat. No. 6,858,970, Multi-Frequency Piezoelectric Energy Harvester, incorporated by reference herein, is also an example of a practical application of implementing an alternative power source **24** described by the block.

[0150] Power Regulation, Storage and/or Storage Charging Block

[0151] The Power Regulation, Storage and/or Storage Charging block contains all the combinations of the Power Regulation and/or Power Storage circuit **28**, Power Storage Charger **30**, and Power Storage block. This block is used in the later figures to reduce the number of figures needed to show how the blocks can interconnect.

[0152] The disclosed invention is the application for retrieving radio frequency (RF) energy by an antenna, converting that energy into direct current (DC) power, regulating that energy using an optimized circuit, storing that energy in an optimized component, and/or supplying the power for specific devices. FIGS. **1-53** show how the system could be implemented.

[0153] Retrieval of RF Energy

[0154] The RF energy is retrieved from the environment by the use of an antenna. The antenna can be shared or standalone with respect to an antenna used for the device's wireless communication. FIGS. **54-56** show a device that has an antenna A for use by the RF harvesting apparatus **10** and an antenna B used for wireless one-way or two-way communication. FIGS. **57-59** show a device where the antenna is shared by the both the device's communication module and RF harvesting apparatus **10**. In terms of form factor, the antenna used by the apparatus **10** can be a separate component or integrated directly into the form factor of the device. The antenna is able to capture two types of available RF energy. The first type of energy exists as ambient RF energy. This type of RF surrounds us in our day-to-day lives and is usually generated to carry one way or two-way combinations of voice, video and data communications. The sources that the antenna can harvest from include medium-frequency AM radio broadcast, very-high-frequency (VHF) FM radio broadcast and television broadcast, ultra-high-frequency (UHF) broadcast, cellular base stations, wireless data access points, super-high-frequency (SHF) frequencies, and the industrial, scientific, and medical (ISM) bands. These sources cover transmission frequencies from 300 kHz to 30 GHz.

[0155] The second type of energy available is directed RF energy. This type of RF energy is directed from a transmitter specifically designed to deliver RF energy for harvesting by the antenna. The transmitter can be configured as a standalone device or integrated into an existing device.

[0156] Conversion of the Energy into DC

[0157] The RF energy captured by the antenna must be converted into a useful form of energy for the specific device. This conversion is shown in block form in all FIGS. (**1-88**) as the RF Power Harvesting Block. The most common form of useable energy is DC energy. To perform this conversion, the block includes circuitry to rectify the captured alternating current (AC) energy to create DC energy. The rectification in this block can be done with a diode(s), a transistor(s), or some other rectifying device or combination.

[0158] Regulation of the Energy

[0159] It may be necessary to regulate the converted power (hold the power at a constant level) for specific devices. FIGS. **2-7**, **10-17**, and **22-53** show how this regulation can be added to the circuit using a Power Regulation and/or Power Storage block. The devices that would need this block require a fairly constant voltage or current. Deviations from the required values may cause the device to not perform within its specifications. The regulation can be implemented in many different ways. The block can be as simple as using a Zener diode, or as complicated as using an integrated circuit such as a linear voltage regulator **26** or a switching regulator **26** to hold the voltage at a constant level. Certain devices have a more tolerable power requirement. For these devices, the regulation stage may be excluded.

[0160] Storage of the Energy

[0161] If a device has intermittent power requirements, such as the devices exampled by FIGS. **2-53**, it may be necessary to store the captured power for use at a later time. The power can be stored in the Power Storage block or the Power Regulation and/or Power Storage block. Storage devices can include but are not limited to a battery, a capacitor, or another type of power storage component. In certain applications, it may be necessary to include additional circuitry that controls how the power is transferred to the storage device. The Power Storage Charger **30** block is shown in FIGS. **18-53**. This may be needed if the storage component requires a special charging mechanism such as pulse charging or trickle charging. Storage components include but are not limited to batteries (rechargeable and non-rechargeable), capacitors, inductors, fuel cells, and other storage elements. There are devices that will not require storage. These devices can run directly off of the converted power. These devices also may or may not require regulation of the captured power.

[0162] Supplying the Power

[0163] The captured DC power, which may or may not be regulated and/or stored, is supplied to the device, which is represented by the Core Device **22** Components block in the figures. This may be a single connection or it may supply multiple parts of the device with power.

[0164] RF energy harvesting also has the ability to be augmented by other types of power harvesting or storage components. Other power harvesting technologies include but are not limited to solar, light (visible and non-visible), piezoelectric, vibration, acoustic, thermal, microgenerators, wind, and other environmental elements. Storage components include but are not limited to batteries (rechargeable and non-rechargeable), capacitors, inductors, fuel cells, and other storage elements. FIGS. **60-88** show how the alternative power can be connected to an RF energy harvesting system. These figure show how the RF energy harvesting components and the alternative power source **24** (or sources) can work independently or have communication with each other. The antenna configurations shown in FIGS. **54-59** are still applicable with the addition of an alternative power source(s) **24**. These antenna configurations can be applied to FIGS. **60-88**.

[0165] RF energy harvesting also has the ability to provide a backup to devices on-grid (tethered) or with reliable power sources, which can be used in case the primary power source is lost. As an example, it may be mandated by regulations that a sensor has auxiliary power in case the primary supply is lost. It could be possible to use a rechargeable battery that obtains its charge from the primary supply when in operation. However, if the primary supply is lost for a time greater than the life of the rechargeable battery, the specification of uninterrupted power is not met. RF energy could be used to supply power to the described device while the primary supply is not available. The primary supply could include but is not limited to an on-grid connection, a generator, a battery, or other reliable power supply.

[0166] RF energy harvesting with or without alternative source augmentation is applicable to provide electric power directly or indirectly to a range of electronic components contained in any specific electrical or electronic device and includes but is not limited to:

[0167] Passive electronic components, active electronic components

[0168] Resistors, fixed resistors, variable resistors, thermistors, thyristor, thermocouple

[0169] Capacitors, Electrolytic Capacitors, Tantalum Capacitors, Ceramic Capacitors, Multilayer Ceramic Capacitors, Polystyrene Film Capacitors, Electric Double Layer Capacitors (Super Capacitors), Polyester Film Capacitors, Polypropylene Capacitors, Mica Capacitors, Metallized Polyester Film Capacitors, Variable Capacitors

[0170] Diodes, Voltage regulation diodes, light-emitting diodes, organic light-emitting diodes, Variable capacitance diodes, Rectification diodes, Switching diodes, Regulation Diodes, Diode bridges, Schottky barrier diodes, tunnel diodes, PIN diodes, Zener diodes, Avalanche diodes, TVSs

[0171] Integrated circuits, microcontroller unit (MCU), microprocessor unit (MPU), logic circuits, memory, printed circuits, circuit boards, printed wiring boards

[0172] Transistors, MOSFETs, FETs, BJTs, JFETs, IGBTs, Relays, Antennas, semiconductors, conductors, inductors, relays, diacs, triacs, SCRs, MOVs

[0173] Fuses, circuit breakers

[0174] Batteries, Non-rechargeable batteries, rechargeable batteries, coin cell batteries, button cell batteries, alkaline batteries, lithium batteries, lithium ion batteries, lithium polymer batteries, NIMH batteries, NICAD batteries, Lead acid batteries, Zinc air batteries, Manganese Lithium batteries, Niobium Titanium Lithium batteries, Vanadium Pentoxide Lithium batteries, Carbon Zinc batteries, Zinc Chloride batteries, Lithium Thionyl Chloride batteries, Manganese Dioxide batteries, Lithium Poly-Carbonmonofluoride batteries, Lithium Manganese Dioxide batteries, Lithium Chloride batteries, Lead Acid Calcium batteries, Lead Acid Tin batteries, Oxy Nickel batteries, Silver Oxide batteries, Magnesium batteries

[0175] Inductors, Coils, High Frequency Coils, Toroidal Coils, Transformers, switches, chokes

[0176] Motors, DC motors, stepper motor, AC motors, Fans

[0177] Crystals, Oscillators, Clocks, Timers

[0178] Displays, LCDs, LED displays

[0179] RF energy harvesting with or without alternative source augmentation is applicable across a range of markets and specific devices and includes but is not limited to:

[0180] Consumer Electronics

[0181] Electronic equipment, wired devices, battery powered devices, wireless communication devices, cell phones, telephones, phones, cordless phones, portable phones, Bluetooth devices, Bluetooth headsets, hands-free headsets, headsets, headphones, Wireless headsets, radios, AM/FM radios, shortwave radios, weather radios, Two-way radios, portable radio, lights, lanterns, portable lights, flashlights, nightlights, spotlights, search lights, calculators, graphing calculators, desk calculators, clocks, alarm clocks, wall clocks, desk clocks, travel clocks, watches, wristwatches, pocket watches, stop watches, timers, voice recorders, Dictaphones, laser pointers, power tools, cordless power tools, electronic razors, electric razors, handheld games, gaming systems, game controllers, wireless game controllers, remote controls, battery chargers, computers, portable computers, keyless entry, toys, toy guns, toy laser guns, games, microphones, musical instruments, musical effects processors, musical instrument tuners, metronomes, electronic chord charts, door openers, garage door openers, PDA, Cameras, Video recorders, Multimeter, electronic test equipment, hand-held electronics, portable electronics, wireless pens, sound generators, noise generators, language translators, electric toothbrushes, portable televisions, pagers, transceivers, toy vehicles, remote control vehicles, toy planes, remote control planes, pet containment systems, invisible fence pet sensors, memory backup, base station battery backups, appliance battery backups, uninterrupted power supplies, GPS devices, memory retention power supplies, metal detectors, stud finders, metal stud finders, stun guns, tazers, wearable devices, baby monitors, intercoms, doorbells, wireless doorbells, electronic office supplies, electronic staplers, radar jammers, radar detectors, digital scales, microfilm cassettes, video head testers, compasses, noise canceling headphones, air samplers, depth finders, barometers, weather measurement instruments, data transfer devices, automatic distress signaling unit, Wireless audio speakers, Satellite radios, Police scanners, Car navigation systems (GPS devices), Decorative lights, Christmas lights, garden lights, lawn lights, ornamental lights, porch lights

[0182] Multi-media players: MP3, DVD, analog music players, CD players, tape players, digital music players, digital video players, minidisc

[0183] Computer: keyboards, mice, peripherals, computer equipment, electronic computers, computer storage, computer terminals

[0184] Building/Industrial Automation

[0185] Sensors: Position, elevator, temperature, fire, accelerometers, level, gas level, fluid level, light level, flow, gas flow, fluid flow, light flow, plasma flow, pressure, gas pressure, fluid pressure, motion, light, infrared light, ultraviolet light, X-rays, cosmic rays, visible light, gamma rays, chemical, stress, strain, depth, electrical characteristics, voltage, current, viscosity, acoustical, sound, listening, thickness, density, surface quality, volume, physical, mass, weight, force, conductivity, distance, orientation, vibration, radioactivity, field strength, electric field strength, magnetic field strength, occupancy, smoke detector, carbon monoxide detector, radon detector, air quality, humidity, glass breakage, break beam detector

[0186] Controls: Position, elevator, temperature, fire, accelerometers, level, gas level, fluid level, light level, flow, gas flow, fluid flow, light flow, plasma flow, pressure, gas pressure, fluid pressure, motion, light, infrared light, ultraviolet light, X-rays, cosmic rays, visible light, gamma rays, chemical, stress, strain, depth, electrical characteristics, voltage, current, viscosity, acoustical, sound, listening, thickness, density, surface quality, volume, physical, mass, weight, force, conductivity, distance, orientation, vibration, radioactivity, field strength, electric field strength, magnetic field strength, occupancy, smoke detector, carbon monoxide detector, radon detector, air quality, humidity

[0187] Devices: Thermostats, light switches, door locks, smart-card door locks, lighting, emergency lighting, motion lighting, safety lighting, highway lighting, construction lighting, sign lighting, roadway sign lighting, construction sign lighting, automatic flushing units, automatic soap dispenser, automatic paper towel dispenser, automatic faucets, automatic door sensors, identification reader, fingerprint reader, credit card readers, card readers, valve actuators, gauges, analog gauges, digital gauges, fire extinguishers, wireless switches, remotely operated inspection equipment, gas/oil pipeline monitoring systems, robotic pipeline inspection gauges, “auto-reclosers” for electric power lines, sonar buoys, telemetry systems, electronic record tracking systems, robbery tracking devices, interrogators, programmers, emergency exit alarms, alarms, flood alarms, gas alarms, electronic entry systems, security keypads, silo transducers, data recorders, signal tracers, anti-static strap testers, radiosonde weather balloons, utilities load controllers, profilometers, noise cancellation equipment, infrared beacons

[0188] Military/Government

[0189] Tracking tags: Weapons, vehicle, soldier, gear/assets, staff, general population, security access badges

[0190] Sensors: Proximity, intrusion, environmental, chemical/biological

[0191] Equipment: Battery charger, surveillance, card readers, identification reader, fingerprint reader, retinal scanners, satellites, rockets, space vehicles, search and rescue transponders (SARTs), emergency position-indicating rescue beacons (EPIRBs), emergency locator transmitters (ELTs), military radios, electronic toll collection systems, postal tracking systems, communications, thermal imaging, night vision, training targets, field medical equipment, house arrest monitors, laser tags, electronic parking meters, multiple integrated laser engagement system, munitions and mines, ship sensors

[0192] Utility

[0193] Gas consumption meters, water consumption meters, and electric consumption meters

[0194] Logistics & Supply Chain Management

[0195] Radio-frequency identification devices (RFID), RFID readers

[0196] Tracking: Asset tags, cargo container location beacons, transponders, transceivers

[0197] Devices: Smart price tags, smart shelving, handheld barcode scanner, barcode scanners, credit card readers, card readers, retail signage, hotel door locks

[0198] Homeland Security

[0199] Sensors: Occupancy, proximity, environmental, chemical/biological, motion, position

[0200] Metal detector wand

[0201] Medical

[0202] Implantable: cochlear implants, neural stimulators, pace makers, medication administration, defibrillator

[0203] Body function monitors: pressure, temperature, respiration, blood oxygenation, insulin, hearing aid, pulse, EKG, heart, Holter,

[0204] Tracking tags: Patient, baby identification, assets, supplies, staff, medication, instruments

[0205] Devices: Home healthcare equipment, ambulatory infusion pumps, blood analyzers, biofeedback systems, bone growth stimulators, thermometers, digital thermometers, stimulators, galvanic stimulators, muscle stimulators, pediatric scales

[0206] Agriculture—livestock tracking and asset tracking.

[0207] Tracking: livestock, asset, wildlife tracking devices

[0208] Equipment: cattle prods

[0209] Automotive

[0210] Automotive antennas, Automotive Audio Systems, Automotive Lighting, Automotive Video Systems, Computers, Processors, Controls, Switches, Electric Motors, Actuators, Ignition Systems, Starter Systems, Injection Systems, Powertrain Electronics, Radar Detectors, Proximity Detectors, Safety Systems, Security Systems, Sensors, Regulators, Distributors, Vehicle Control, Wiper Systems, Washer Systems, Radio, Video Systems, Entertainment Systems, Navigation Systems, GPS systems, Power Mirror Systems, Emission control systems

[0211] Appliances

[0212] Monitoring systems and control systems for major and small appliances including washing machines, dryers, refrigerators, freezers, coolers, air conditioners, humidifiers, dehumidifiers, air purifiers, air filters, fans, furnaces, water heaters, boilers, space heaters, sowing machines, ice makers, microwave ovens, convection ovens, ovens, toaster ovens, ranges, range hoods, cooktops, stoves, stovetops, crock pots, hot plates, dishwashers, garbage disposals, can openers, vacuum cleaners, blenders, mixers, food processors, irons, coffee makers, toasters, grills, hair dryers, electric tooth brushes, electric razors, electric drills, electric screwdrivers, chainsaws, lawnmowers, push mowers, riding mowers, trimmers, brush cutters, pruners, edgers, vending machines

[0213] Ventilation, Heating, Air-Conditioning, and Commercial Refrigeration Equipment

[0214] Monitoring systems, control systems

[0215] Engine, Turbine, and Power Transmission Equipment

[0216] Monitoring systems, control systems

[0217] Other General Purpose Machinery Manufacturing

[0218] Monitoring systems, control systems

[0219] Telecommunications

[0220] Monitoring systems, control systems

[0221] Portable

[0222] Aircraft

[0223] Monitoring systems, control systems, actuator systems, sensors

[0224] It should be noted that devices within a specific category may be applicable across multiple areas even if they are not specifically listed. (e.g. temperature sensors apply to Industrial and Building Automation).

[0225] To retrofit or redesign the devices listed, it is possible to implement the described systems in numerous ways. It may be advantageous to leave the device design as is including the existing power supply. As an example, a device may use non-rechargeable batteries to operate. The device will most likely have a protection circuit to prevent damage if the batteries are installed incorrectly. The protection mechanism is commonly a diode inline with the positive terminal of the battery. In this case, the RF Power Harvesting Source with or without an Alternative power source **24** could be inserted, with an antenna, into the device. The power generated by the RF Power Harvesting Source (and alternative power source **24**, if applicable) could be connected to the device after the protection mechanism described to avoid potential charging of a non-rechargeable battery.

[0226] Another way to configure the system is to replace the non-rechargeable batteries with rechargeable batteries. In this instance, the output from the RF Power Harvesting Source (and alternative power source **24**) could be connected to either side of the protections device. If the connection is before the protection mechanism, the system will recharge the battery and supply power to the device. If the connection is after the protection mechanism, the system will supply power to the device and battery will supply any extra power needed that could not be supplied by the system. It should be noted that the protection device in this case is unneeded for proper operation. Its only function would be to protect the batteries from being installed incorrectly. An antenna could be contained inside or placed on the outside of the device.

[0227] Another configuration of the system is to remove the existing batteries and install the RF Power Harvesting Source (and alternative power source **24**) in the enclosure provided for the batteries. An antenna could be contained inside or placed on the outside of the device.

[0228] Yet another method of configuring the system would be to reduce the number of batteries and replace them with the RF Power Harvesting Source (and alternative power source **24**). In this case, the output from the system would be connected to the batteries in series or parallel depending on the original battery configuration. An antenna could be contained inside or placed on the outside of the device.

[0229] An additional option, would be to completely redesign the product and integrate the require circuitry and storage components into the device. This method is probably the most advantageous because it can fully take advantage of the benefits offered by the RF Power Harvesting Source (and alternative power source **24**). An antenna could be contained inside or placed on the outside of the device.

[0230] If the RF Power Harvesting Source (and alternative power source **24**) is used as a backup to the primary power supply, a switch could be implemented into the system in order to switch the RF Power Harvesting Source (and alternative power source **24**) in when the primary source is lost. In this case, an antenna could be contained inside or placed on the outside of the device.

[0231] To show the flexibility of RF energy harvesting, several products were retrofitted to include RF energy harvesting circuitry. These products include a wireless keyboard, a wall clock, and a desk calculator.

[0232] The wireless keyboard is an example of recharging and augmenting a battery to supply power to a device. This system is shown in FIG. **13**. The output from the regulation circuitry recharges the battery and supplies power to the keyboard. The battery is also used to supply power to the keyboard. The keyboard also includes a separate antenna for receiving power and for data communications. The antenna configuration can be seen in FIG. **55**.

[0233] The wall clock is an example of a direct powering system. The wall clock was retrofitted to include energy harvesting circuitry and the internal AA battery was removed. This system is shown in FIG. **2**. The wall clock did not need regulation but did require a capacitor for storage to supply the pulse of power to move the second hand.

[0234] The calculator is an example of using RF energy harvesting with another energy harvesting technology. The calculator had an internal 1.5V coin cell battery and a small solar panel. The internal battery was removed, however, the solar panel was left intact. This system is shown in FIG. **60**. In this system, the calculator can receive power from both the solar panel and the RF energy harvesting circuitry to eliminate the need for a battery.

[0235] As an additional example, an RF energy harvesting circuit similar to the ones shown in U.S. Pat. No. 6,615,074 (FIGS. 8, 9, 12a, 12b, 13, 14), incorporated by reference, herein, was connected in series with a 0.5V solar cell. Individually, the solar cell was able to provide 0.480V to a 10 kilo-ohm resistor, which was being used to simulate the Core Device **22** Components. This corresponds to 23 microwatts. The RF power harvesting circuit by itself was able to provide 2.093V across the 10 kilo-ohm resistor when being supplied by 1 milliwatt of RF power. This corresponds to 438 microwatts. The two circuit outputs were then combined in series by connecting the output from the RF energy harvesting circuit to the ground of the solar cell. The output of the solar cell was then connected to the resistor. The other end of the resistor was connected to the ground of the RF energy harvesting circuit. The voltage across the resistor with the circuits connected, as shown in FIG. **63**, was 2.445V. This corresponds to 598 microwatts. As can be seen, the combination of the two technologies produces a result higher than the addition of the individual powers. From this, it can be determined that the two technologies can cooperate in a way that produces favorable results. In the example given, the solar cell produces current to supply the load and helps to bias the RF rectifying diodes, which allows the RF energy harvesting circuit to operate a higher efficiency. The solar cell also changes the impedance seen by the RF energy harvesting circuit, which produces a beneficial result. To be more specific, when examining the power output of the individual circuit (solar and RF power harvesting), the sum of the power captured by the individual circuits was 23 uW+438 uW=461 uW. However, when the two circuits are combined and are allowed to work in conjunction with one another, the output power becomes 598 uW. This results shows that combining the two power-harvesting technologies produces a 30 percent increase in the output power for this example. This same technique can be applied to multiple energy harvesting technologies to produce even greater output power. The equations for this example are shown below.

[0236] Individual Circuits

$$P_I=P_1+P_2+\dots+P_N$$

[0237] Combined Circuits

$$P_C>P_I=P_1+P_2+\dots+P_N$$

where P_I is the sum of the individual output powers

[0238] P_C is the output of the combined circuit

[0239] P_1 is the output power from the first power harvesting technology

[0240] P_2 is the output power from the second power harvesting technology

[0241] P_N is the output power from the Nth power harvesting technology

[0242] N is the number of power harvesting technologies or circuits

[0243] The present invention pertains to a device **36** for receiving wireless power. The device **36** comprises a point of reception, wherein the point of reception is positionable in at least a first position **40** and a second position **42**.

[0244] The present invention pertains to a method for receiving wireless power. The method comprises the steps of positioning a point of reception in contact with a housing **46** to a first position **40**. There is the step of receiving wireless power at the point of reception and providing it to a power harvester **20** in the housing **46**. There is the step of converting the wireless power to usable DC with the power harvester **20**. There is the step of providing the usable DC to core components **48** in the housing **46**. There is the step of using the DC by the core components **48**. There is the step of repositioning the point of reception to a second position **42**. There is the step of receiving wireless power at the point of reception at the second position **42** and providing it to the power harvester **20**. There is the step of converting the wireless power received by the point of reception in the second position **42** to usable DC with the power harvester **20**. There is the step of providing the usable DC to the core component in the housing **46**. There is the step of using the DC by the core components **48**.

[0245] Another example of a product that was retrofitted to include RF energy harvesting circuitry was a cell phone. The cell phone is an example of recharging and augmenting a battery to supply power to a device. This system is shown in FIGS. **91-96**.

[0246] The cell phone is one example from a family of similar products, including, personal digital assistants, MP3 players, etc. Any of these devices may be configured to receive wireless power with or without communications data. The device includes a point of reception which receives the wireless power. For example, the point of reception may be an antenna. The point of reception is connected to the power harvester.

[0247] The point of reception is positionable in at least two positions: a first position and a second position. The first and second positions are designed such that in the first position, the cell phone is in normal operation and in the second position, the cell phone is capable of efficiently being charged/recharged.

[0248] The first and second positions may also be designed such that reception at each position may vary depending on the location of the device. Preferably, either the first position or the second position of the point of reception will provide better reception of the wireless power for a given location of the device (e.g., for charging and use, or for optimal charging).

[0249] Some or all of the positions may be applicable to a given embodiment of a cell phone or other device. In other words, various permutations of positions for the point of reception may be desirable and designed into the device. Additionally, the positions may be "infinite" in that the point of reception may be positioned anywhere desired as allowed by the particular design. Any mechanism for attaching the point of reception to the device is contemplated as is dictated by the particular application. For example, the mechanism may be a hinge (single pin, dual pin), a ball and socket joint, etc.

[0250] The device may include a stop mechanism configured to assist in positioning the point of reception in a desired position. The stop mechanism may be integral with the housing, the point of reception, or both. As an example, the point of reception may be an antenna that is contained in an antenna housing, for example, a plastic housing. The antenna housing may have a ridge that fits into one or more notches formed on the housing or device as the antenna housing moves with respect to the notched part of the housing or the device.

[0251] The point of reception may be designed into the device or connectable to the communications port of the device.

[0252] The device may include a communications antenna. The point of reception and the communications antenna may be co-located in an area of the device.

[0253] The device may have a single antenna configured to act as both a point of reception for wireless power and a communications antenna. A filter separates the received wireless power and the received communications data. A rectifier (i.e., the power harvester) converts the wireless power to a form usable by the device, such as DC.

[0254] The device may be configured such that the device automatically determines when it needs to be charged. At such time, the device sends a message to a wireless power transmitter indicating that the device needs to be charged by having the wireless power transmitter send wireless power to the device. The message may be sent using any means capable of indicating that the device needs to be charged, such as RF or infrared. The wireless power transmitter receives the message and begins to send wireless power to the device.

[0255] The wireless power transmitter may or may not stop sending power depending on the application. When the device is fully charged, the device may send a message to the wireless power transmitter to indicate that it no longer needs power. The wireless power transmitter may stop sending wireless power or continue to send a lower power level to supply operation current or to keep the battery or batteries charged while they are being drained by active, sleep, or leakage currents. Alternatively, the wireless power transmitter may send wireless power for a predetermined amount of time. If multiple devices are present, the wireless power transmitter may continue to send power even if one device has fully charged.

[0256] The wireless power transmitter may require periodic indications from the device that the device is still present in order to continue sending power. This would help to avoid sending power if the device is moved mid-way through charging, that is, if no device is present to receive the wireless power.

[0257] The device may indicate power requirements or battery size to set wireless power transmitter output power level. If multiple devices are present, the highest power level may be chosen.

[0258] If multiple wireless power transmitters are involved, the wireless power transmitters may communicate with each other to coordinate power transfer.

[0259] The device may send charging status information to the wireless power transmitter or other data device, such as a computer.

[0260] The device preferably includes a housing having a front, a back, a side, and an end. The point of reception is connected to the housing.

[0261] The point of reception may be pivotally connected to the housing, for example, at the end or the side of the housing. For example, referring to FIG. **91**, a cell phone may have an antenna that pivots from a first position substantially juxtaposed to the housing of the cell phone to a second position at an angle to the housing. In the second position, the antenna may be used to support the cell phone in an upright position, as shown.

[0262] Expanding on the example shown in FIG. **91** and referring to FIG. **92**, the antenna may pivot to a third position substantially extending parallel from the back of the housing. The antenna may further pivot to a fourth position substantially at a right angle to the front of the housing. The antenna may further rotate to a fifth position substantially juxtaposed to the front of the housing (for example, to protect a screen and other elements of the device).

[0263] For another example, referring to FIG. **93**, the antenna may pivot from a first position substantially juxtaposed to the side of the housing to a second position substantially at a right angle to the side of the housing. The antenna may further rotate to a third position substantially extending parallel to the side of the housing.

[0264] The point of reception may be slideably connected to the housing, for example, at the back, the side, or the front of the housing. For example, referring to FIG. **94**, the cell phone may have an antenna that slides from a first position substantially juxtaposed to the back of the housing to a second position substantially extending from the back of the housing. Similarly, the antenna may be slideably juxtaposed to the front of the housing (not shown).

[0265] For another example, referring to FIG. **95**, the antenna may slide from a first position substantially juxtaposed to the side of the housing to a second position substantially extending parallel from the side of the housing.

[0266] The point of reception may be retractably connected to the housing, for example, at the end of the housing. For example, referring to FIG. **96**, the point of reception may be co-located or integral with a communications antenna, where the antenna(s) is retracted into the housing in the first position and pulls out of the housing into the second position.

[0267] Filters are used to separate the incoming power and communications signals and to route the separated signals to the appropriate circuitry. A first filter may be designed to pass the frequency(ies) of the power signal while having a high impedance for the frequency(ies) of the communications signal. A second filter may be designed to pass the frequency (ies) of the communications signal while having a high impedance for the frequency(ies) of the power signal. The output of the first filter may be supplied to the power rectification circuitry that converts the power to a usable form, such as DC. The output of the power rectification circuitry may or may not be connected to charging circuitry. The charging circuitry monitors and/or regulates the voltage and/or current supplied to the battery to ensure proper charging.

[0268] The point of reception may be rotatably connected to the housing, for example, at the end or the side of the housing. For example, a cell phone may have an antenna that rotates from a first position substantially extending parallel to the back of the housing of the cell phone to a second position substantially extending parallel to the back of the housing, but where a face of the antenna is in a different position than the face when in the first position.

[0269] It should be noted that any of the previous embodiments of the cell phone may include an indicator to inform the user of the charging status. The indicator may also inform the user of the amount of wireless power being received. The indicator could then not only be used to position the device to achieve the desired charging rate, but also to position the antenna to achieve the desired charging rate. Examples of indicators include LEDs, LCDs, or other indicating components.

[0270] It should be noted that any of the previous embodiments of the cell phone may have the point of reception achieved by a user (for example, manually sliding the point of reception with respect to the housing) or automatically (for example, via spring loading).

[0271] A cell phone charger/recharger was designed to retrofit the SLVR cell phone from Motorola. The device was constructed as shown in FIGS. **91**(*a*) and (*b*). The back cover (housing) of the cell phone was removed and replaced with a specially designed cover (housing) that included a hinge at the top just below the lens of the camera portion of the phone.

[0272] The point of reception was designed to angle away from the cell phone using a pin hinge (FIG. **97**) in order to maximize the power transfer for the application. When angled away from the cell phone, the point of reception (implemented in this example as a patch antenna designed on Rogers 4003 material) acted as an antenna and as a support for the phone. The patch antenna was probe fed with the rectification circuitry being located near the middle of the antenna behind the ground plane. The patch antenna was designed to receive the maximum amount of energy when vertically polarized and the back of the cell phone point toward the source.

[0273] The rectification circuitry used was disclosed in U.S. patent application Ser. No. 11/584,983 filed Oct. 23, 2006, incorporated herein by reference. The output of the rectifier was connected to a charging circuit used to ensure that the battery contained within the cell phone was not over charged in terms of voltage or current.

[0274] The charging circuit was also connected to an indicator to show the user that the phone was charging. The indicator could also be used to show the charging status such as fully charged. The retrofitted cell phone used an LED as the indicator to show whether or not the cell phone was charging.

[0275] The output of the charging circuit was connected to the battery of the cell phone using a flexible printed circuit board (flex PCB), although a ribbon cable or other similar mechanism may be used. The flex PCB was thin enough to run under the back cover of the cell phone from the battery to a small notch where the flex PCB exited the cell phone and was connected to the charging circuit on the back of the antenna.

[0276] The antenna, rectifier, and charging circuit were encased in a plastic enclosure. The enclosure was connected to the hinge that also connected to the specially designed back cover. The hinge was designed to be resistive in order to allow the user to increase the angle between the phone and the antenna to a desired position without the need for a stopping mechanism, such as grooves.

[0277] A cell phone charger/recharger was also designed as described in the previous example, but using the design shown in FIG. **92**. The point of reception (implemented using a patch antenna designed on Rogers 4003 material) was designed to be positioned by the user on the back of the cell phone during normal cell phone use and located perpendicular to the front (face) of the cell phone for recharging as shown in FIG. **98**.

[0278] The patch antenna was probe fed with the rectification circuitry being located near the middle of the antenna behind the ground plane. The patch antenna was designed to receive the maximum amount of energy when vertically polarized and positioned perpendicular to the face of the phone with the top of the phone pointed toward the source.

[0279] The rectification circuitry used was disclosed in U.S. patent application Ser. No. 11/584,983 filed Oct. 23, 2006, incorporated by reference herein. The output of the rectifier was connected to a charging circuit used to ensure that the battery contained within the cell phone was not over charged in terms of voltage or current.

[0280] The charging circuit was also connected to an indicator to show the user that the phone was charging. The indicator could also be used to show the charging status such as fully charged. The retrofitted cell phone used an LED as the indicator to show whether or not the cell phone was charging.

[0281] The output of the charging circuit was connected to the battery of the cell phone using a flexible printed circuit board (flex PCB) although a ribbon cable or similar mechanism could be used. The flex PCB was thin enough to run under the back cover of the cell phone from the battery to a small notch where the flex PCB exited the cell phone and was connected the charging circuit on the back of the antenna.

[0282] The point of reception was designed to swing from the back of the cell phone to a position perpendicular to the face of the phone using two pin hinges located along the sides of the phone (shown in FIG. **99**) in order to maximize the power transfer for the application. If found to be advantageous, the electrical connection from the cell phone battery to the output of the charging circuit could be made through the hinges of the device. As an example, each pin hinge could be made with a metal pin where the right pin was connected to the positive connection of the battery and charging circuit and the left pin was connected to the negative connection of the battery and charging circuit.

[0283] It should be noted that in both of the previous examples, the wireless charger/recharger was designed to retrofit an existing cell phone. It is also possible to design the device into the cell phone.

[0284] As can be seen by the previous examples, RF energy harvesting can be used alone or in conjunction with alternative power sources **24** to power a wide range of devices. The addition of RF energy harvesting technology to the device allows for increased battery life, increased functionality, or the removal of the primary battery.

[0285] For purposes herein the following definition is applicable. A portable electronic device is defined to be less than about 25 pounds and preferably less than about 5 pounds in weight. It can be carried by one person either with or without some type of strap and preferably with only one arm or hand of the person. It has a device or circuitry that is powered by electricity.

[0286] Besides the various applications listed above, the RF energy harvesting can be used with any device requiring an antenna, although an antenna is necessarily needed in all embodiments, and includes radios and walkie talkies, besides cell phones, PDAs and MP3 players, to mention but a few of the many possible electronic devices.

[0287] Although the invention has been described in detail in the foregoing embodiments for the purpose of illustration, it is to be understood that such detail is solely for that purpose and that variations can be made therein by those skilled in the art without departing from the spirit and scope of the invention except as it may be described by the following claims.

1. A device for receiving wireless power, comprising:
- a point of reception, wherein the point of reception is positionable in at least a first position and a second position.

2. The device as described in claim **1**, wherein when the device is in a first location, when the point of reception is in the first position, the point of reception receives better reception than when in the second position.

3. The device as described in claim **2**, wherein when the device is in a second location, when the point of reception is in the second position, the point of reception receives better reception than when in the first position.

4. The device as described in claim **1**, wherein the point of reception is an antenna.

5. The device as described in claim **1**, further including a communications antenna.

6. The device as described in claim **5**, wherein the point of reception is co-located with the communications antenna.

7. The device as described in claim **1**, wherein the point of reception is connected to a communications port of the device.

8. The device as described in claim **1**, wherein the device includes a housing.

9. The device as described in claim **8**, wherein the point of reception is connected to the housing.

10. The device as described in claim **9**, wherein the point of reception is pivotally connected to the housing.

11. The device as described in claim **10**, wherein the point of reception is connected to an end of the housing.

12. The device as described in claim **10**, wherein the point of reception is connected to a side of the housing.

13. The device as described in claim **9**, wherein the point of reception is slideably connected to the housing.

14. The device as described in claim **13**, wherein the point of reception is connected to a back of the housing.

15. The device as described in claim **13**, wherein the point of reception is connected to a side of the housing.

16. The device as described in claim **9**, wherein the point of reception is retractably connected to the housing.

17. The device as described in claim **16**, wherein the point of reception is connected to an end of the housing.

18. The device as described in claim **9**, further including a stop mechanism configured to position the point of reception.

19. The device as described in claim **9**, wherein the point of reception is rotatably connected to the housing.

20. The device as described in claim **1** including a power harvester for converting wireless energy into usable DC, and core components in electrical communication with the power harvester to receive the DC to power the core components.

21. The device as described in claim **20**, further including an alternative power source connected to the core components to power the core components in conjunction with the power harvester.

22. The device as described in claim **20**, further including a power regulator and/or power storage circuit connected to the power harvester.

23. The device as described in claim **20**, further including a power storage charger connected to the power harvester.

24. The device as described in claim **20**, further including power storage connected to the power harvester.

25. The device as described in claim **20**, wherein the core components include a memory connected to an integrated circuit and to the power harvester to power memory.

26. The device as described in claim **20** wherein the core components includes a transmitter.

27. The device as described in claim **26** wherein the core components include a speaker.

28. The device as described in claim **27** wherein the core components include a receiver for receiving spoken words and converting the words into signals to be transmitted by the transmitter.

29. A device for receiving wireless power and communications data, comprising:
- an antenna configured to receive wireless power and communications data;
- a filter to separate the wireless power and the communications data; and
- a rectifier to convert the wireless power into a usable form.

30. A method for receiving wireless power comprising the steps of:
- positioning a point of reception in contact with a housing to a first position;
- receiving wireless power at the point of reception and providing it to a power harvester in the housing;
- converting the wireless power to usable DC with the power harvester;
- providing the usable DC to core components in the housing;
- using the DC by the core components;
- repositioning the point of reception to a second position;
- receiving wireless power at the point of reception at the second position and providing it to the power harvester;
- converting the wireless power received by the point of reception in the second position to usable DC with the power harvester;
- providing the usable DC to the core components in the housing; and
- using the DC by the core components.

Methods, systems, and apparatuses for providing power to devices that are part of RFID systems are described. Energy is harvested at portable/mobile devices, stored and conditioned to provide on-going power as needed for various circuits/components. The energy may be generated in a variety of ways, including using a vibratory energy harvesting device, a magnetic energy harvesting device, and an optical energy harvesting devices.

ENERGY HARVESTING IN RFID SYSTEMS

BACKGROUND OF THE INVENTION

[0001] 1. Field of the Invention

[0002] The invention relates to radio frequency identification (RFID) systems, and in particular, to harvesting energy in an RFID systems environment.

[0003] 2. Background Art

[0004] Radio frequency identification (RFID) tags are electronic devices that may be affixed to items whose presence is to be detected and/or monitored. The presence of an RFID tag, and therefore the presence of the item to which the tag is affixed, may be checked and monitored wirelessly by devices known as "readers." Readers typically have one or more antennas transmitting radio frequency signals to which tags respond. Because the reader "interrogates" RFID tags, and receives signals back from the tags in response to the interrogation, the reader is sometimes termed a "reader interrogator" or simply "interrogator."

[0005] With the maturation of RFID technology, efficient communication between tags and interrogators has become a key enabler in supply chain management, especially in manufacturing, shipping, and retail industries, as well as in building security installations, healthcare facilities, libraries, airports, warehouses etc.

[0006] With the increased use of peripheral devices in RFID systems, it is becoming increasingly important to devise new ways to provide power to such devices. For example, a mobile computer with an integrated RFID interrogator may be used by an operator wearing a headset to communicate with the computer or a central communications point. A reader interrogator may be remote from a conventional power source, etc.

[0007] Thus, what is needed are improved ways of providing power to various devices included in RFID systems.

BRIEF SUMMARY OF THE INVENTION

[0008] The invention provides various techniques for harvesting power in the context of RFID systems. It also provides techniques for accumulating power harvested by various techniques and utilizing that power to operate various devices.

[0009] In exemplary embodiments, power is harvested by a device worn by an operator. One example of such a device is a headset. Power is harvested using various techniques/structures including: a solar array, an inertial harvesting device, a piezo energy harvester, and a charge pump.

[0010] There is provided a low voltage rectifier circuit for use in harvesting power from a variety of sources.

[0011] Power storage devices are provided for cumulating power derived from one or multiple sources.

[0012] In various embodiments, energy may be generated by a variety of energy harvesting devices, including a vibratory energy harvesting device, electromagnetic energy harvesting device, a magnetic energy harvesting device, a photo-optical energy harvesting device, a heat energy harvesting device, or a mechanical energy harvesting device.

[0013] In an embodiment, a vibratory energy harvesting device generates the energy from vibration of the mobile structure. For example, the vibratory energy harvesting device comprises a piezoelectric transducer. In an example implementation, a moment arm mounts the piezoelectric transducer. A capacitor is coupled to the energy storage device. Vibration of the arm causes the arm to deflect the piezoelectric transducer. The piezoelectric transducer generates a current due to the deflection. The current charges the capacitor.

[0014] In another example aspect, a magnetic energy harvesting device generates the energy from magnetism related to the movement of the mobile structure.

[0015] In a further example aspect, the magnetic energy harvesting device includes a magnet and a coil. The energy is generated by movement of the magnet with respect to the coil.

[0016] In another example aspect, an photo-optical energy harvesting device includes an photo-optical-to-electrical transducer that converts light received at the mobile structure into energy.

[0017] In another example aspect, a heat energy harvesting device converts heat generated by operation of the mobile structure into energy.

[0018] In another example aspect, a mechanical energy harvesting device converts friction due to operation of the mobile structure into energy. In another example aspect, the mechanical energy harvesting device uses a rotational wheel mechanism that rotates due to movement of the mobile structure to generate energy.

[0019] These and other objects, advantages and features will become readily apparent in view of the following detailed description of the invention. Note that the Summary and Abstract sections may set forth one or more, but not all exemplary embodiments of the present invention as contemplated by the inventor(s).

BRIEF DESCRIPTION OF THE DRAWINGS/FIGURES

[0020] The accompanying drawings, which are incorporated herein and form a part of the specification, illustrate the invention and, together with the description, further serve to explain the principles of the invention and to enable a person skilled in the pertinent art to make and use the invention.

[0021] In the drawings, like reference numbers indicate identical or functionally similar elements.

[0022] Additionally, references numbers which are the same, but vary by virtue of an appended letter of the alphabet (for example, **412**, **412**R, **412**P, **412**S) or an appended letter and number (for example, **412**, **412**S**1**, **412**S**2**) indicate elements which may be substantially the same or similar, but represent variations or modifications of the basic element. In some cases, the reference number without the appended letter or without the appended letter and number (for example, **412**) may indicate a generic form of the element, while reference numbers with an appended letter or an appended letter and number (for example, **412**S, **412**S**1**, **412**S**2**, **412**P) may indicate a more particular or modified form of the element.

[0023] Generally, the leftmost digit(s) of a reference number identifies the drawing in which the reference number first appears. For example, an element labeled **412** typically indicates that the element first appeared in FIG. **4**.

[0024] FIG. **1** shows an environment where RFID readers (interrogators) communicate with an exemplary population of RFID tags.

[0025] FIG. **2** is a block diagram of receiver and transmitter portions of an RFID reader.

[0026] FIG. **3** is a block diagram of an exemplary radio frequency identification (RFID) tag.

[0027] FIG. **4** is a general block diagram illustrating a system for harvesting energy and utilizing it to power circuits/devices.

[0035] The present invention will now be described with reference to the accompanying drawings. In the drawings, like reference numbers indicate identical or functionally similar elements. Additionally, the left-most digit(s) of a reference number identifies the drawing in which the reference number first appears.

DETAILED DESCRIPTION OF THE INVENTION

Introduction

[0036] Power arrangements for RFID system components are described herein.

[0037] Supplying power to RFID system devices located in real world installations can be difficult, particularly for mobile devices. Providing cabled power to a user of an RFID system "in the field" may be problematic. The power cable may be damaged by wear associated with the movement and actuation of the structure A battery may be mounted to the mobile structure to avoid the need for a power cable. However, RFID devices may require a large amount of power to carry out their functions, and thus require regular recharging/changing of batteries.

[0038] The invention provides various techniques for harvesting power in the context of RFID systems. It also provides techniques for cumulating power harvested by various techniques and utilizing that power to operate various devices.

[0039] In exemplary embodiments, power is harvested by a headset worn by an operator. Power is harvested using various techniques/structures including: RF signal transmitted by an RFID interrogator, solar array, inertial harvesting device, and piezo energy harvester.

[0040] There is provided a low voltage rectifier circuit for use in harvesting power from a variety of sources.

[0041] Power storage devices are provided for cumulating power derived from one or multiple sources.

[0042] In aspects, the energy may be generated by a variety of energy harvesting devices, including a vibratory energy harvesting device, a magnetic energy harvesting device, an optical energy harvesting device, a heat energy harvesting device, or a mechanical energy harvesting device.

[0043] In an example aspect, a vibratory energy harvesting device generates the energy from vibration of the mobile structure during operation of the mobile structure.

[0044] In a further example aspect, the vibratory energy harvesting device comprises a piezoelectric transducer. In an example implementation, a moment arm mounts the piezoelectric transducer. A capacitor is coupled to the energy storage device. Vibration of the arm causes the arm to deflect the piezoelectric transducer. The piezoelectric transducer generates a current due to the deflection. The current charges the capacitor.

[0045] In another example aspect, a magnetic energy harvesting device generates the energy from magnetism related to the movement of the mobile structure.

[0046] In a further example aspect, the magnetic energy harvesting device includes a magnet and a coil. The energy is generated by movement of the magnet with respect to the coil.

[0047] In another example aspect, an optical energy harvesting device includes an optical-to-electrical transducer that converts light received at the mobile structure into energy.

[0048] In another example aspect, a heat energy harvesting device converts heat generated by operation of the mobile structure into energy.

[0049] In another example aspect, a mechanical energy harvesting device converts friction due to operation of the mobile structure into energy. In another example aspect, the mechanical energy harvesting device uses a rotational wheel mechanism that rotates due to movement of the mobile structure to generate energy.

[0050] Embodiments of the present invention overcome problems with powering readers present in conventional systems. For example, according to embodiments, energy is generated on the mobile structure on which the reader is disposed, such as in the form of electrical energy. The energy is stored on the mobile structure, and used to power the reader. In this manner, the need for replacement of batteries, battery charging cycle times, power cables, and/or extremely large batteries is reduced or eliminated.

[0051] The present specification discloses one or more embodiments that incorporate the features of the invention. The disclosed embodiment(s) merely exemplify the invention. The scope of the invention is not limited to the disclosed embodiment(s). The invention is defined by the claims appended hereto.

[0052] References in the specification to "one embodiment," "an embodiment," "an example embodiment," etc., indicate that the embodiment described may include a particular feature, structure, or characteristic, but every embodiment may not necessarily include the particular feature, structure, or characteristic. Moreover, such phrases are not necessarily referring to the same embodiment. Further, when a particular feature, structure, or characteristic is described in connection with an embodiment, it is submitted that it is within the knowledge of one skilled in the art to effect such feature, structure, or characteristic in connection with other embodiments whether or not explicitly described.

[0053] Furthermore, it should be understood that spatial descriptions (e.g., "above," "below," "up," "down," "top," "bottom," "vertical," "horizontal," etc.) used herein are for purposes of illustration only, and that practical implementations of the structures described herein can be spatially arranged in any orientation or manner.

[0054] In the following description, numerous specific details are set forth in order to provide a thorough understanding of the invention. However, it will be apparent to those skilled in the art that the invention, including structures, systems, and methods, may be practiced without these specific details. The description and representation herein are the common means used by those experienced or skilled in the art to most effectively convey the substance of their work to others skilled in the art. In other instances, well-known methods, procedures, components, and circuitry have not been described in detail to avoid unnecessarily obscuring aspects of the invention.

[0055] References in the specification to "one embodiment," "an embodiment," "an example embodiment," etc., indicate that the embodiment described may include a particular feature, structure, or characteristic, but every embodiment may not necessarily include the particular feature, structure, or characteristic. Moreover, such phrases are not necessarily referring to the same embodiment. Further, when a particular feature, structure, or characteristic is described in connection with an embodiment, it is submitted that it is within the knowledge of one skilled in the art to effect such feature, structure, or characteristic in connection with other embodiments whether or not explicitly described.

Exemplary Operating Environment

[0056] Before describing embodiments of the invention in detail, it is helpful to describe an example RFID communications environment in which the inventions may be implemented. FIG. **1** illustrates an environment **100** where RFID tag readers **104** (readers **104***a* and **104***b* shown in FIG. **1**) communicate with an exemplary population **120** of RFID tags **102**. As shown in FIG. **1**, the population **120** of tags includes seven tags **102***a*-**102***g*. A population **120** may include any number of tags **102**.

[0057] Environment **100** includes any number of one or more readers **104**. For example, environment **100** includes a first reader **104***a* and a second reader **104***b*. Readers **104***a* and/or **104***b* may be requested by an external application to address the population of tags **120**. Alternatively, reader **104***a* and/or reader **104***b* may have internal logic that initiates communication, or may have a trigger mechanism that an operator of a reader **104** uses to initiate communication. Readers **104***a* and **104***b* may also communicate with each other in a reader network (see FIG. **2**).

[0058] As shown in FIG. **1**, reader **104***a* "reads" tags **120** by transmitting an interrogation signal **110***a* to the population of tags **120**. Interrogation signals may have signal carrier frequencies or may comprise a plurality of signals transmitted in a frequency hopping arrangement. Readers **104***a* and **104***b* typically operate in one or more of the frequency bands allotted for this type of RF communication. For example, the Federal Communication Commission (FCC) defined frequency bands of 902-928 MHz and 2400-2483.5 MHz for certain RFID applications.

[0059] Tag population **120** may include tags **102** of various types, such as, for example, various classes of tags as enumerated above. Thus, in response to interrogation signals, the various tags **102** may transmit one or more response signals **112** to an interrogating reader **104**. Some of the tags, for example, may respond by alternatively reflecting and absorbing portions of signal **104** according to a time-based pattern or frequency. This technique for alternatively absorbing and reflecting signal **104** is referred to herein as backscatter modulation. Typically, such backscatter modulation may include one or more alpha-numeric characters that uniquely identify a particular tag. Readers **104***a* and **104***b* receive and obtain data from response signals **112**, such as an identification number of the responding tag **102**. In the embodiments described herein, a reader may be capable of communicating with tags **102** according to various suitable communication protocols, including Class 0, Class 1, EPC Gen 2, other binary traversal protocols and slotted aloha protocols, and any other protocols mentioned elsewhere herein, and future communication protocols. Additionally, tag population **120** may include one or more tags having the packed object format described herein and/or one or more tags not using the packed object format (e.g., standard ISO tags).

[0060] FIG. **2** shows a block diagram of an example RFID reader **104**. Reader **104** includes one or more antennas **202**, a receiver and transmitter portion **220** (also referred to as transceiver **220**), a baseband processor **212**, and a network interface **216**. These components of reader **104** may include software, hardware, and/or firmware, or any combination thereof, for performing their functions.

[0061] Baseband processor **212** and network interface **216** are optionally present in reader **104**. Baseband processor **212** may be present in reader **104**, or may be located remote from reader **104**. For example, in an embodiment, network interface **216** may be present in reader **104**, to communicate between transceiver portion **220** and a remote server that includes baseband processor **212**. When baseband processor **212** is present in reader **104**, network interface **216** may be optionally present to communicate between baseband processor **212** and a remote server. In another embodiment, network interface **216** is not present in reader **104**.

[0062] In an embodiment, reader **104** includes network interface **216** to interface reader **104** with a communications network **218**. As shown in FIG. **2**, baseband processor **212** and network interface **216** communicate with each other via a communication link **222**. Network interface **216** is used to provide an interrogation request **210** to transceiver portion **220** (optionally through baseband processor **212**), which may be received from a remote server coupled to communications network **218**. Baseband processor **212** optionally processes the data of interrogation request **210** prior to being sent to transceiver portion **220**. Transceiver **220** transmits the interrogation request via antenna **202**.

[0063] Reader **104** has at least one antenna **202** for communicating with tags **102** and/or other readers **104**. Antenna (s) **202** may be any type of reader antenna known to persons skilled in the relevant art(s), including for example and without limitation, a vertical, dipole, loop, Yagi-Uda, slot, and patch antenna type.

[0064] Transceiver **220** receives a tag response via antenna **202**. Transceiver **220** outputs a decoded data signal **214** generated from the tag response. Network interface **216** is used to transmit decoded data signal **214** received from transceiver portion **220** (optionally through baseband processor **212**) to a remote server coupled to communications network **218**. Baseband processor **212** optionally processes the data of decoded data signal **214** prior to being sent over communications network **218**.

[0065] In embodiments, network interface **216** enables a wired and/or wireless connection with communications network **218**. For example, network interface **216** may enable a wireless local area network (WLAN) link (including a IEEE 802.11 WLAN standard link), a BLUETOOTH link, and/or other types of wireless communication links. Communications network **218** may be a local area network (LAN), a wide area network (WAN) (e.g., the Internet), and/or a personal area network (PAN).

[0066] In embodiments, a variety of mechanisms may be used to initiate an interrogation request by reader **104**. For example, an interrogation request may be initiated by a remote computer system/server that communicates with reader **104** over communications network **218**. Alternatively, reader **104** may include a finger-trigger mechanism, a keyboard, a graphical user interface (GUI), and/or a voice activated mechanism with which a user of reader **104** may interact to initiate an interrogation by reader **104**.

[0067] In the example of FIG. **2**, transceiver portion **220** includes a RF front-end **204**, a demodulator/decoder **206**, and a modulator/encoder **208**. These components of transceiver **220** may include software, hardware, and/or firmware, or any combination thereof, for performing their functions. Example description of these components is provided as follows.

[0068] Modulator/encoder **208** receives interrogation request **210**, and is coupled to an input of RF front-end **204**. Modulator/encoder **208** encodes interrogation request **210** into a signal format, such as, for example, one of pulse-interval encoding (PIE), FM0, or Miller encoding formats, modulates the encoded signal, and outputs the modulated encoded interrogation signal to RF front-end **204**.

[0069] RF front-end **204** may include one or more antenna matching elements, amplifiers, filters, an echo-cancellation unit, a down-converter, and/or an up-converter. RF front-end **204** receives a modulated encoded interrogation signal from modulator/encoder **208**, up-converts (if necessary) the interrogation signal, and transmits the interrogation signal to antenna **202** to be radiated. Furthermore, RF front-end **204** receives a tag response signal through antenna **202** and down-converts (if necessary) the response signal to a frequency range amenable to further signal processing.

[0070] Demodulator/decoder **206** is coupled to an output of RF front-end **204**, receiving a modulated tag response signal from RF front-end **204**. In an EPC Gen 2 protocol environment, for example, the received modulated tag response signal may have been modulated according to amplitude shift keying (ASK) or phase shift keying (PSK) modulation techniques. Demodulator/decoder **206** demodulates the tag response signal. For example, the tag response signal may include backscattered data formatted according to FM0 or Miller encoding formats in an EPC Gen 2 embodiment. Demodulator/decoder **206** outputs decoded data signal **214**.

[0071] The configuration of transceiver **220** shown in FIG. **2** is provided for purposes of illustration, and is not intended to be limiting. Transceiver **220** may be configured in numerous ways to modulate, transmit, receive, and demodulate RFID communication signals, as would be known to persons skilled in the relevant art(s).

[0072] The invention described herein is applicable to any type of RFID tag, with suitable additional features, as described in further detail below in conjunction with FIG. **4** and beyond. FIG. **3** is a schematic block diagram of an example radio frequency identification (RFID) tag **102** as already known to those practiced in the art. Tag **102** includes a substrate **302**, an antenna **304**, and an integrated circuit (IC) **306**. Antenna **304** is formed on a surface of substrate **302**. Antenna **304** may include any number of one, two, or more separate antennas of any suitable antenna type, including for example dipole, loop, slot, and patch. IC **306** includes one or more integrated circuit chips/dies, and can include other electronic circuitry. IC **306** is attached to substrate **302**, and is coupled to antenna **304**. IC **306** may be attached to substrate **302** in a recessed and/or non-recessed location.

[0073] IC **306** controls operation of tag **102**, and transmits signals to, and receives signals from RFID readers using antenna **304**. In the example of FIG. **3**, IC **306** includes a memory **308**, a control logic **310**, a charge pump **312**, a demodulator **314**, and a modulator **316**. Inputs of charge pump **312**, and demodulator **314**, and an output of modulator **316** are coupled to antenna **304** by antenna signal **328**.

[0074] Demodulator **314** demodulates a radio frequency communication signal (e.g., interrogation signal **110**) on antenna signal **328** received from a reader by antenna **304**. Control logic **310** receives demodulated data of the radio frequency communication signal from demodulator **314** on an input signal **322**. Control logic **310** controls the operation of RFID tag **102**, based on internal logic, the information received from demodulator **314**, and the contents of memory **308**. For example, control logic **310** accesses memory **308** via a bus **320** to determine whether tag **102** is to transmit a logical "1" or a logical "0" (of identification number **318**) in response to a reader interrogation. Control logic **310** outputs data to be transmitted to a reader (e.g., response signal **112**) onto an output signal **324**. Control logic **310** may include software, firmware, and/or hardware, or any combination thereof. For example, control logic **310** may include digital circuitry, such as logic gates, and may be configured as a state machine in an embodiment.

[0075] Modulator **316** is coupled to antenna **304** by antenna signal **328**, and receives output signal **324** from control logic **310**. Modulator **316** modulates data of output signal **324** (e.g., one or more bits of identification number **318**) onto a radio frequency signal (e.g., a carrier signal transmitted by reader **104**) received via antenna **304**. The modulated radio frequency signal is response signal **112** (see FIG. **1**), which is received by reader **104**. In one example embodiment, modulator **316** includes a switch, such as a single pole, single throw (SPST) switch. The switch is configured in such a manner as to change the return loss of antenna **304**. The return loss may be changed in any of a variety of ways. For example, the RF voltage at antenna **304** when the switch is in an "on" state may be set lower than the RF voltage at antenna **304** when the switch is in an "off" state by a predetermined percentage (e.g., 30 percent). This may be accomplished by any of a variety of methods known to persons skilled in the relevant art(s).

[0076] Charge pump **312** (or other type of power generation module) is coupled to antenna **304** by antenna signal **328**. Charge pump **312** receives a radio frequency communication signal (e.g., a carrier signal transmitted by reader **104**) from antenna **304**, and generates a direct current (DC) voltage level that is output on tag power signal **326**. Tag power signal **326** powers circuits of IC die **306**, including control logic **320**.

[0077] Charge pump **312** rectifies a portion of the power of the radio frequency communication signal of antenna signal **328** to create a voltage power. Charge pump **312** increases the voltage level of the rectified power to a level sufficient to power circuits of IC die **306**. Charge pump **312** may also include a regulator to stabilize the voltage of tag power signal **326**. Charge pump **312** may be configured in any suitable way known to persons skilled in the relevant art(s). For description of an example charge pump applicable to tag **102**, refer to U.S. Pat. No. 6,734,797, titled "Identification tag Utilizing Charge Pumps for Voltage Supply Generation and Data

Recovery," which is incorporated by reference herein in its entirety. Alternative circuits for generating power in a tag, as would be known to persons skilled in the relevant art(s), may be present. Further description of charge pump **312** is provided below.

[0078] It will be recognized by persons skilled in the relevant art(s) that tag **102** may include any number of modulators, demodulators, charge pumps, and antennas. Tag **102** may additionally include further elements, including an impedance matching network and/or other circuitry. Furthermore, although tag **102** is shown in FIG. **3** as a passive tag, tag **102** may alternatively be an active tag (e.g., powered by a battery, not shown).

[0079] Memory **308** is typically a non-volatile memory, but can alternatively be a volatile memory, such as a DRAM. Memory **308** stores data, including an identification number **318**. In a Gen-2 tag, tag memory **308** may be logically separated into four memory banks.

[0080] As further described below, according to embodiments of the present invention, energy is generated on the mobile structure on which the reader is disposed. The generated energy is stored on the mobile structure, and used to power the reader. In this manner, the need for power cables and/or extremely large batteries with regard to mobile structures is reduced or eliminated.

[0081] Embodiments of the present invention are described in further detail below. Such embodiments may be implemented in environment **100** shown in FIG. **1**, with reader **104** shown in FIG. **2**, and/or in alternative environments and RFID devices.

Energy Harvesting—General Concept

[0082] Energy harvesting systems are described herein for providing energy to various RFID system devices. Energy harvesting device generate energy in various ways, some examples of which are described in specific embodiments herein. The energy harvesting devices may be associated with a mobile/portable structure in various ways. For example, an energy harvesting device may be disposed directly on mobile structure, integrated into a mobile/portable structure or otherwise attached to it.

[0083] Various embodiments are described that feature a headset worn by an operator. Although the inventions described herein are particularly useful for powering headsets, they are not limited to headsets. Harvested energy can be used to power other devices, such as mobile/portable computers, communication devices, etc.

[0084] Embodiments for the energy harvesting systems can be implemented wherever convertible energy may be available. Systems can be implemented in a commercial or industrial environment, such as in a warehouse, a factory, a business, or store, and in a military or other non-commercial environment. For example, an RFID interrogator may be attached to a stationary structure or to a mobile structure. The energy generating systems enable deployment of devices that form RFID systems or are attached to RFID systems without the need for power cables and with potentially less space required for batteries.

[0085] FIG. **4** is a general block diagram illustrating a system for harvesting energy and utilizing it to power circuits/devices. Main system components include an energy harvesting module **402**, an energy conditioning circuit **404**, and an energy storage device **406**. Energy accumulated and stored in storage device **406** can be used to power various circuits/devices **408**, as needed. The energy storage device **406** is typically a rechargeable battery, but may alternatively be another type of battery or storage device otherwise known or future developed that can receive and store energy. Example materials/battery types for a rechargeable battery include Lithium (e.g., Li-ion, Li-polymer), Nickel-Cadmium (NiCD), Nickel-Metal Hydride (NiMH), Zinc-air, or other material. Further examples for energy storage device **406** include fuel cells, nano-enabled energy storage materials, capacitors, inertial energy storage devices, or other energy storage devices. In an embodiment, energy is transferred to energy storage device from energy harvesting device in the form of an electric current over a suitable wire, cable, or bundle of wires and/or cables. Energy storage device is disposed on mobile structure including being carried by, mounted on, or directly attached to mobile structure.

[0086] Energy harvesting module **402** may include one or more energy harvesting devices including but not limited to: solar array, piezo device, inertial magnetic device, RF energy harvester, etc. A plurality of energy harvesting devices can be coupled so as to cumulate their respective energy outputs (see FIG. **10**).

[0087] In embodiments, different types of energy harvesting devices can be used. For example, FIG. **7** shows a piezo device **708** as the energy harvesting device.

RF Energy Harvesting

[0088] FIG. **5** is a schematic diagram of an embodiment of the invention illustrating harvesting energy from a signal transmitted by an RFID interrogator.

[0089] A headset is worn by an operator. The operator may be carrying an RFID interrogator **504** that regularly transmits an interrogation signal **506**. The operator may be carrying and operating a mobile computer with which the headset communicates. Headset **502** has an integrated antenna **510**, in which a current is induced by signal **506**. Current induced in antenna **510** may be conditioned by a rectifier circuit and accumulated in a storage device. One suitable rectifier circuit is shown in FIG. **9**. Other types of rectifier circuits can be used as well. One suitable storage device is a capacitor or bank of capacitors. Such capacitors may be conventional capacitors, polymer capacitors or other suitable type of capacitor. Another suitable energy storage device is a battery. There are other suitable storage devices as well.

[0090] As an alternative, a conventional RFID tab can be integrated into headset **502**. The charge pump (add ref numeral) of the RFID tag (FIG. **3**) can serve as the energy harvesting device.

Solar Array Energy Harvesting

[0091] FIG. **6** is a schematic diagram of an embodiment of the invention illustrating harvesting energy from a solar array, or more generally, an optical energy harvesting device. Headset **502** is fitted with an array of solar cells **602**, preferably on an upper portion of the headset. Solar cells generate an electric current that is appropriately conditioned and stored in an energy storage device.

[0092] Optical energy harvesting converts light received by optical energy into a current, to generate energy to charge energy storage device **406**. Optical energy harvesting device **1202** can incorporate a variety of optical energy harvesting materials/devices to generate energy. For example, optical energy harvesting device **1202** may include optical-to-electrical transducers such as solar cells (or photovoltaic cells) to convert light to energy, photodiodes, optoelectronic transducers, other light sensitive elements that convert light to a current, and any other optical energy harvesting materials/devices known to persons skilled in the relevant art(s). The optical-to-electrical transducers may be positioned on a mobile structure, such as headset **502**, such that solar and/or other light energy is received in sufficient quantities to generate a charging current.

Piezo Electic Energy Harvesting

[0093] FIG. **7** is a schematic diagram of an embodiment of the invention illustrating harvesting mechanical energy using a piezo electric device. Piezoelectric materials exhibit a "piezoelectric effect," such that when they are subjected to a compressive or tensile stress, an electric field is generated across the material, creating a voltage gradient and subsequent current flow. Example suitable piezoelectric materials include polyvinylidene fluoride (PVDF) and lead zirconate titanate (PZT).

[0094] This embodiment is constructed and arranged to capture some of the vibratory energy of motion, such as for example, when an operator wearing headset **502** moves about. A headset microphone **702** is constructed in a manner that it acts like a moment arm. It is connected to a boom element **704** either directly or through a connecting element **706**. Motion of the operator results in a vibration of microphone **702** and boom element **704**. Boom element **704** drives a piezo-electric device **708** which generates an electric current as it mechanically shifts. The electric current is appropriately conditioned and stored.

[0095] Piezo device **708** could also be attached to a piece of movable machinery, such as, for example, a conveying device, such as a fork lift. Piezo device **708** can include a variety of vibration sensing/converting mechanisms, including piezoelectric transducers, magnets, and other mechanisms. Piezoelectric device **708** is attached to a moment arm formed by boom element **704**. Piezoelectric device **708** is also anchored to headset **502**. When headset **502** moves, the moment arm formed by boom **704** vibrates. This vibration deflects piezoelectric device **708**. Piezoelectric device **708** converts this mechanical deflection to a voltage gradient that charges a storage device, such as a capacitor, that ultimately provides a trickle charge to energy storage device **406**.

[0096] Piezoelectric device **708** may include a piezoelectric transducer and optionally, a rectifier, filter, DC-DC converter, etc. Some piezoelectric transducers output an AC (alternating current) current due to the piezoelectric effect caused by vibration. If such transducers are used, piezo device **708** should include a rectifier to convert the AC output current of the piezoelectric transducer into a DC (direct current) current signal. Such a rectifier may include one or more diodes arranged in a rectifier configuration. A filter can be included to smooth a rectified DC current signal. Such a filter may include a capacitor.

[0097] For further description regarding piezoelectric transducers and circuit **900**, refer to Katz, Andrew, "Residential Piezoelectric Energy Sources," Delta Smart House, Jul. 21, 2004 (all pages) (http://delta.pratt.duke.edu/downloads/piezoelectrics_andrew.doc), which is incorporated by reference herein in its entirety.

Inertial Energy Harvesting

[0098] FIG. **8** is a schematic diagram of an embodiment of the invention illustrating harvesting mechanical energy using an inertial device. This embodiment is constructed and arranged to capture some of the mechanical energy of motion when an operator wearing headset **502** moves about. A headset microphone **802** is constructed in a manner that it acts like a moment arm. It is connected to a boom element **804** either directly or through a connecting element **806**. Boom element **804** is made of a magnetic material. Motion of the operator results in a vibration of microphone **802** and boom element **804**. Boom element **804** is constructed and arranged so that its motion induces a current in an induction coil **810** as it mechanically shifts. The electric current induced in induction coil **810** is appropriately conditioned and stored.

[0099] The inertial harvesting device can be configured in a variety of ways to use magnetism to generate energy. For example, one or more magnets can be positioned near a coil of wire. When vibrations (such as due to the vibratory motion of boom element **804**) cause relative motion between the magnetic material and induction coil, a current is generated in the wire of the coil that provides a trickle charge to a storage device (not shown in FIG. **8**). The storage device may be an intermediate storage element, such as one or more capacitors, for holding charge prior to transfer to energy storage device **406**, or may be energy storage device **406** itself.

Low Voltage Rectifier Circuit

[0100] FIG. **9** is a schematic diagram of a low voltage rectifier circuit suitable for use with various energy harvesting transducer/devices. It is assumed in this embodiment that energy is being harvested by an energy harvesting transducer **902** that provides an AC signal that must be rectified so that power can be stored in a battery, capacitor, or the like. Rectification is carried out by four insulated gate field effect transistors (IGFETs) **904**, **906**, **908** and **910**. IGFETs are used because of their low-voltage properties. They can operate at the very low voltages generated by energy harvesting transducers already described, such as the piezo-electric transducer and inertial transducer. IGFETs **904**, **906**, **908** and **910** are connected in a rectifier circuit arrangement. Transducer **902** has outputs **912** and **914** characterized by an AC signal being formed between them. Gates of the IGFETS **904** and **906** are connected to node **914** of energy harvesting transducer **902**. The drain of IGFET **904** and the source of IGFET **906** are connected to a node **912** of the energy harvesting transducer, and to the gates of IGFETs **908** and **910**. Node **914** of the energy harvesting transducer is also connected to the drain of IGFET **908** and to the source of IGFET **910**. A capacitor **940** has a first node **942** connected to the source of IGFET **908** and a second node **944** connected to the drain of IGFET **910**, harvested power being made available across the first and second nodes of the capacitor. Capacitor **940** smoothes voltage swings across the outputs **950** and the positive output **960** of the rectifier circuit.

Multiple Energy Harvesting Devices

[0101] More than one energy harvesting device can be connected in a manner that allows power to be accumulated from them. FIG. **10** is a general block diagram of an embodiment illustrating how power can be harvested from two or more devices and combined. In this embodiment, power is harvested using an inertial device **1002**, an RFID tag charge pump **1004**, a solar array **1006** and a piezo device **1008**. Power from each of these harvesting devices is conditioned as necessary before being stored in an energy storage device

1014. Power requiring low voltage rectification, such as from the inertial device **1002** and the piezo device **1008** is coupled to a low voltage rectifier **1010**. An exemplary embodiment of a low voltage rectifier is shown in FIG. **9**. Solar array **1006** is coupled to a charging circuit **1012**. Storage device **1014** can be any suitable energy storage device. Examples include a rechargeable battery, a capacitor, a bank of capacitors, etc. Power stored in storage device **1014** can then be utilized as needed by coupling the storage device **1014** to an energy conditioning circuit **1016** such as a regulator. For example, conditioning circuit **1016** could be a buck boost regulator. Power stored in storage device **1014** can, for example, be used to power a headset, a computer to which a headset is tethered, a portable/mobile communication device to which a headset is tethered, an RFID interrogator, etc.

Position of Components

[0102] FIG. **11** is a schematic diagram illustrating how energy harvesting components can be placed in a worn headset **502**. One or more RF harvesting antennas can be placed in/integrated within a boom element **1102** supporting a microphone **1104**. As an alternative, RF harvesting antennas can be placed in/integrated within a head clasp support structure **1106** of headset **502**. Power storage devices can be placed in a body portion **1108** or the head clasp support structure **1106** of headset **502**. Power conditioning circuits can also be located with the head clasp support structure **1106** or the body portion **1108** of headset **502**.

ALTERNATIVE EMBODIMENTS

[0103] Although the embodiments feature a headset, the principles of the invention apply to other mobile/portable devices as well. Examples of such mobile/portable structures include conveying devices, such as a forklift, warehouse box crushers, conveyor belts, cars, trucks, etc.

CONCLUSION

[0104] While various embodiments of the present invention have been described above, it should be understood that they have been presented by way of example only, and not limitation. It will be apparent to persons skilled in the relevant art that various changes in form and detail can be made therein without departing from the spirit and scope of the invention. Thus, the breadth and scope of the present invention should not be limited by any of the above-described exemplary embodiments, but should be defined only in accordance with the following claims and their equivalents.

What is claimed is:

1. A method for providing power to a mobile device in an RFID system, comprising:

harvesting energy at the mobile device;

charging an energy storage device disposed on the mobile structure with the generated energy; and

powering one or more circuits of the mobile device with energy stored in the energy storage device.

2. The method of claim **1**, wherein the harvesting comprises:

(a) generating the energy from vibration of the mobile structure during operation of the mobile structure.

3. The method of claim **2**, wherein step (a) comprises:

generating the energy with a piezoelectric transducer mounted to the mobile structure.

4. The method of claim **1**, wherein said generating comprises:

generating energy produced by relative movement of a magnet and a coil that are mounted to the mobile structure.

5. The method of claim **1**, wherein said generating comprises:

converting light received at the mobile device into energy.

6. The method of claim **1**, wherein said converting light comprises:

converting light received at the mobile device into energy using an optical-to-electrical transducer.

7. The method of claim **1**, wherein said generating comprises:

obtaining power from a charge pump of an RFID tag associated with the mobile device.

8. The method of claim **1**, wherein said generating comprises:

inducing a current in an antenna receiving a signal from an RFID interrogator; and

conditioning the current induced in the antenna for storage in the energy storage device.

9. The method of claim **1**, further comprising:

conditioning power from the energy storage device.

10. The method of claim **9**, wherein the conditioning comprises conditioning power with a buck boost regulator.

11. An arrangement for providing power to a mobile device in an RFID system, comprising:

an energy harvesting device associated with the mobile device;

an energy storage device disposed on the mobile device constructed and arranged to store power harvested by the energy harvesting device; and

a powering conditioning circuit for obtaining power from the energy storage device and providing power to one or more circuits of the mobile device.

12. An arrangement according to claim **11** further comprising a low voltage rectifier circuit, including:

first and second P-channel FETs; and

first and second N-channel FETs, the P and N-channel FETs being arranged in an H-bridge configuration.

13. An arrangement according to claim **11** wherein the energy harvesting device is a charge pump.

14. An arrangement according to claim **11** wherein the energy harvesting device is a piezo-electric device.

15. An arrangement according to claim **11** wherein the energy harvesting device is a magnetic device.

16. An arrangement according to claim **11** wherein the energy harvesting device is a photo-optic device.

17. An arrangement according to claim **11** wherein the energy storing device is a capacitor.

18. An arrangement according to claim **11** wherein the energy storing device is a battery.

19. A system for providing power to a portable device that is part of a radio frequency identification (RFID) system, comprising:

an energy storage device disposed on the portable device structure and coupled to the reader; and

an energy harvesting device disposed on the mobile structure that generates energy;

wherein the energy storage device stores the generated energy.

20. An arrangement according to claim **19** further comprising a low voltage rectifier circuit, including:

first and second P-channel FETs; and

first and second N-channel FETs, the P and N-channel FETs being arranged in an H-bridge configuration.

21. The system of claim **19**, wherein the mobile structure is a headset.

22. The system of claim **19**, wherein said energy harvesting device comprises:

a vibratory energy harvesting device that generates the energy from vibration of the mobile structure during operation of the mobile structure.

23. The system of claim **19**, wherein said vibratory energy harvesting device comprises:

a piezoelectric transducer.

24. The system of claim **19**, further comprising:

a moment arm that mounts the piezoelectric transducer; and

a capacitor coupled to the energy storage device;

wherein vibration of the arm causes the arm to deflect the piezoelectric transducer;

wherein the piezoelectric transducer generates a current due to the deflection, and

wherein the current charges the capacitor.

25. The system of claim **19**, wherein said energy harvesting device comprises:

a magnetic induction energy harvesting device.

26. The system of claim **25**, wherein said magnetic energy harvesting device comprises:

a magnet; and

a coil;

wherein the energy is generated by movement of the magnet through the coil field.

27. The system of claim **19**, wherein said energy harvesting device comprises:

an photo-optical-to-electrical transducer that converts light received at the mobile structure into energy.

28. A low voltage rectifier circuit, comprising:

first and second P-channel FETs; and

first and second N-channel FETs, the P and N-channel FETs being arranged in an H-bridge configuration.

(57) **ABSTRACT**

A mechanism to tap an electrical source which uses an aircraft (preferably a lighter than air balloon) tethered by a conductive line. The conductive line is extended/withdrawn by a winch motor to adjust the altitude of the aircraft. The conductive line is isolated from the ground and an electrical conductor is connected to the conductive line and to an electrical load. In this manner, static electricity generated in the atmosphere is gathered for use.

ATMOSPHERIC ELECTRICAL GENERATOR

BACKGROUND OF THE INVENTION

[0001] This invention relates to the production of electrical energy and more particularly to the production of electrical energy from the atmosphere.

[0002] Everyone is familiar with Benjamin Franklin's kite experiment of 1752. Using a kite whose string had become wet, negative charges from the passing clouds flowed into the string, down to the suspended key, and then into a Leyden jar via a thin metal wire. Franklin was protected by a dry silk string; but, when Franklin's knuckle came too close to the key, he received a strong shock. Fortunately, Benjamin Franklin was not killed, others who tried this same experiment were not so lucky.

[0003] Since then, the formation of lightning has remained something of a mystery. Lightning bolts are triggered when a negatively charged cloud base induces a positive charge from the ground, thereby forming a "pathway" for the discharge of the collected electrical energy.

[0004] Lightning travels up to 60,000 miles per hour with a flash that is brighter than ten million 100-watt lightbulbs. This wattage is as much power as is produced by all of the electricity plants in the United States and with a voltage of up to 300 million volts.

[0005] It is this very fact, the power within lightning is immense, that has prevented any successful collection of the electrical energy from lightning. The electricity in lightning is far too extreme for current technology to harness.

[0006] While lightning has attracted a energy starved industrial world, no one has developed any technique to harness this naturally occurring electrical source.

[0007] It is clear there is a continuing need for an electrical source other than carbon-based fuels and that the naturally occurring electricity in the atmosphere is being ignored.

SUMMARY OF THE INVENTION

[0008] The invention is a mechanism which taps into the naturally occurring static electricity in the atmosphere. Whereas heretofore, the attempt to garner electricity from the atmosphere has focused exclusively on capturing lightning, the present invention syphons off the static electricity which is generated from any agitated air and voids lightning.

[0009] Lightning is only the final discharge of the static electricity, whether that lightning is intra-cloud lightning, cloud-to-ground lightning, or inter-cloud lightning. Other types of final discharges are known as heat lightning, summer lightning, sheet lightning, ribbon lightning, silent lightning, ball lightning, bead lightning, elves, jets, and sprites. Well before these discharges are observed, as the atmosphere becomes agitated by wind or thermal, static electricity is being generated.

[0010] The present invention recognizes that this static electricity is being formed and creates a mechanism to capture it.

[0011] The mechanism of this invention utilizes an aircraft such as a lighter than air balloon. While the preferred embodiment uses a foil balloon, a variety of other aircraft are obvious to those of ordinary skill in the art, including, but not limited to: gliders, rubber balloons (such as weather balloons), biaxially-oriented polyethylene terephthalate polyester film balloons, and latex balloons.

[0012] Within this discussion, the balloon is referenced, but, the invention is not intended to be limited solely to balloons.

[0013] The balloon is sent aloft and is tethered by a conductive line. In this context, the conductive line may be any obvious to those of ordinary skill in the art. For the preferred embodiment, the conductive line is a generically referred to as a "poly-rope" and is commercially available through a variety of sources. A suitable conductive line is described in U.S. Pat. No. 5,203,542, entitled "Apparatus for Improved Electric Fence Wire Construction for use with Intensive Grazing" issued Apr. 20, 1993, to Coley, et al. and incorporated hereinto by reference.

[0014] The conductive line is played out of a winch to control the altitude of the balloon. The motor controlling the winch is able to reverse direction to both extend and withdraw the conductive line which is wrapped around a spool on the winch. The winch/spool combination are part of a base unit.

[0015] In some embodiments of the invention, the spool is constructed of rubber so as to insulate the conductive line from the winch assembly. In this embodiment, only the conductive line is charged by the atmospheric static electricity while the winch remains neutral.

[0016] In yet another embodiment, the winch/spool are part of a base unit which is itself isolated from the ground by an insulator. In this embodiment, the entire base unit is charged by the atmospheric static electricity.

[0017] A conductor, such as an insulated wire, is electrically connected to the conductive line. In one embodiment, where the conductive line is electrically isolated from the spool and winch motor, the conductor is connected to the conductive line. In the embodiment where the conductive line is electrically connected to the base unit, then the conductor is connected anywhere on a metallic base unit.

[0018] The other end of the conductor is connected to a load. The load in this case can be any of a variety of electrical loads well known to those of ordinary skill in art, including, but not limited to a motor, a battery system, or the electrical grid for the system.

[0019] In the preferred embodiment, a sensor array is used to monitor the activities both at the base unit (such as electrical flow within the conductor) and in the surrounding locale.

[0020] A sensor monitoring the electrical flow (i.e. voltage and/or current) within the conductor is used to monitor the electrical activity within the conductor.

[0021] In the preferred embodiment, a lightning sensor monitors for lightning activity within the locale. As noted earlier, the electrical characteristic of lightning is so extreme that ideally this discharge is avoided as it might damage the mechanism of this invention.

[0022] The sensor array is utilized by a controller, such as microprocessor, programmed to operate the mechanism as outlined herein.

[0023] The controller operates the winch motor to extend or withdraw the conductive line and by extension the altitude of the balloon. The controller is programmed to operate the winch by monitoring the electrical characteristics of the conductor and adjusting the balloon's altitude to maintain these characteristics within the conductor within a preset range.

[0024] This preset range is established either in the base programming of the controller or is established by an operator of the system.

[0025] As example, by controlling the amount of current being withdrawn from the atmosphere, the mechanism oper-

ates within a safe range and also provides a relatively stable current flow from which a variety of activities can take place (such as DC-AC conversion).

[0026] The controller also utilizes the lightning sensor to protect the mechanism from a lightning strike. Should lightning be detected within a pre-determined range (as established by the software or defined by an operator), then the balloon is pulled down to minimize the risk of damage from a lightning strike.

[0027] The invention, together with various embodiments thereof will be more fully explained by the following description of the accompanying drawings.

DRAWINGS IN BRIEF

[0028] FIG. **1** diagrams the preferred embodiment of the invention.

[0029] FIG. **2** illustrates the collection of the negative charged particles in the atmosphere.

[0030] FIG. **3** is a flow-chart of the operation of the controller for the preferred embodiment of the invention.

[0031] FIGS. **4**A, **4**B, and **4**C are electrical schematics for handling the static charge from the atmosphere.

[0032] FIG. **5** illustrates a conductive line used in the preferred embodiment of the invention.

[0033] FIGS. **6**A and **6**B illustrate an alternative conductive line creating an ionized pathway for the flow of the static charges from the atmosphere.

[0034] FIG. **7** illustrates the controller of an alternative embodiment and the associated safety devices.

[0035] FIGS. **8**A and **8**B illustrate two embodiments of enhanced electrical collection leads.

DRAWINGS IN DETAIL

[0036] FIG. **1** diagrams the preferred embodiment of the invention.

[0037] Balloon **10** is an aircraft which, in this illustration, is a lighter than air balloon. Wings **10**A, extending from the body of balloon **10**, provide additional lift in air flow **18**. Tail **10**B helps to stabilize balloon **10**.

[0038] Balloon **10** is tethered to the ground via conductive line **12**. As noted earlier, a variety of configurations and materials are available to serve as conductive line **12**. In this illustration, a poly-wire is used. Poly-wire is commercially available through a variety of vendors, including, but not limited to: Jeffers Livestock and Sareba Systems, Inc. of Ellendale, Minn.

[0039] In this embodiment, located proximate to balloon **10**, is an electrical collection enhancement lead **11** which assists in the collection of the static electrical charge in the atmosphere. Electrical collection enhancement lead **11** is configured to attract the static charge and conduct the charge into the conductive line **12**.

[0040] The electricity flows down the conductive line into spool **13**, where the conductive line **12** is collected and either withdrawn or dispensed through operation of winch motor **14**.

[0041] Winch motor **14** and spool **13** are mounted onto base unit **16** which is electrically isolated from ground **7** using insulator **17**. Note, in this embodiment of the invention, when electricity is being collected from the atmosphere, the entire base unit **16** becomes charged. In another embodiment of the invention, spool **13** is constructed of rubber, thereby preventing base unit **16** from becoming charged, thereby restricting the charging from the atmosphere to only conductive line **12**.

[0042] In this embodiment, conductor **6** is connected to base unit **16** (since the entire base unit **16** is charged and the base unit is metallic) to communicate the electrical current to load **5**. Conductor **6** is ideally an insulated wire.

[0043] The electrical current through conductor **6** is measured using sensor **8**.

[0044] In the alternative embodiment discussed above, where only the conductive line **12** is charged, then conductor **6** is connected to conductive line **12**.

[0045] Controller **15**, located in this embodiment on base unit **16**, operates winch motor **14** in response to signals from sensor **8** (measuring the current being discharged to load **5**) to maintain the current flow within a pre-defined range. As the current flow diminishes, then the conductive line **12** extended from spool **13** to increase the altitude of balloon **10** to that more static charge from the atmosphere is gathered; as the current flow falls exceeds a preset level, conductive line **12** is withdrawn onto spool **13** to decrease the static charge being collected from the atmosphere.

[0046] The range of current flow through conductor **6** is ideally set by the program, although some embodiments of the invention permit an operator to establish this range of operation.

[0047] In an alternative embodiment, the sensor monitoring conductor **6** monitors the voltage therein.

[0048] In the preferred embodiment of the invention, controller **15** is also equipped with a lightning sensor **19**. In this embodiment, when lightning is sensed within a preset range, then substantially all of conductive line **12** is wound onto spool **13** to pull balloon **10** near the ground and protect the entire mechanism from being damaged from a lightning discharge.

[0049] In the preferred embodiment, the "safe" distance form lightning is set in the programming of controller **15** and is ideally two miles; other embodiments permit the operator to "safe" distance.

[0050] There are a variety of lightning sensors well known to those of ordinary skill in the art, including, but not limited to those described in: U.S. Pat. No. 7,016,785, entitled "Lightning Detection" issued to Makela, et al. on Mach 21, 2006; U.S. Pat. No. 6,829,911, entitled "Lightning Detection and Prediction Alarm Device" issued to Jones, et al. on Dec. 7, 2004; U.S. Pat. No. 7,200,418, entitled "Detection of Lightning" issued to Karikuranta, et al. on Apr. 3, 2007; and U.S. Pat. No. 6,961,662, entitled "Systems and Methods for Spectral Corrected Lightning Detection" issued to Murphy on Nov. 1, 2005; all of which are incorporated hereinto by reference.

[0051] In another embodiment of the invention, controller **15** is not located on base unit **16**, rather it is remote and communicates its control signals to winch motor **14** using radio waves.

[0052] FIG. **2** illustrates the collection of the negative charged particles in the atmosphere.

[0053] Static charges **23** are generated in the atmosphere by agitated air. These static charges are often collected at the bottom of clouds, but exist in other environments as well.

[0054] Balloon **21** is extended into this strata of static charges **23** which are then attracted to conductive line **12** to flow to base unit **22** and then onto load **5**.

[0055] By increasing or decreasing the altitude of balloon **21** (defined by the length of the extended conductive line **12**),

conductive line **12** is selectively exposed to varying densities and levels of the static charge strata, and by extension, the current flow or voltage is increased or decreased.

[0056] FIG. **3** is a flow-chart of the operation of the controller for the preferred embodiment of the invention.

[0057] Once the program starts **30**, the lightning sensor is checked to determine if lightning has occurred within the unsafe range **31**A, if it has, then the balloon is lowered **32**A, and the program continues monitoring the status of lightning until no lightning is detected.

[0058] When the lightning status is acceptable, then the current within the conductor is checked to see if the current is within the prescribed range **31**B. If the current is acceptable (within range) the program returns to check the lightning status **31**A; otherwise a determination is made to see if the current is above the prescribed range **31**C.

[0059] If the current is above the prescribed range, then the altitude of the balloon is withdrawn a set amount **32**B (ideally twenty-five feet) and the program loops back to see if the current is within range **31**B.

[0060] If the current is below the prescribed range, then the altitude of the balloon is extended a set amount **32**C (ideally twenty-five feet) and the program loops back to see if the current is within range **31**B.

[0061] In this manner of feed-back and minor adjustments in the altitude of the balloon, the current is maintained within a prescribed range which can be handled by the downstream electrical system.

[0062] As noted earlier, some embodiments of the invention monitor the voltage instead of the current.

[0063] FIGS. **4**A, **4**B, and **4**C are electrical schematics for handling the static charge from the atmosphere.

[0064] By maintaining the voltage being collected in a prescribed range, an electrical conversion system is easily designed. While FIGS. **4**A, **4**B, and **4**C illustrate some electrical configurations, those of ordinary skill in the art readily recognize a variety of other configurations which will serve the same function.

[0065] Referencing FIG. **4**A, Direct Current In (DC IN) **40** is buffered by a gang of capacitors **41** before being communicated to a DC/AC converter **42**. The DC/AC converter converts the direct current into a an alternating current suitable for placement over an existing electrical grid **43** such as normally found from a power-plant.

[0066] Those of ordinary skill in the art readily recognize a variety of DC/AC converters, including, but not limited to: U.S. Pat. No. 7,394,671, entitled "Controller IC, DC-AC Conversion Apparatus, and parallel running system of DC-AC Conversion Apparatuses" issued to Fukumoto, et al. on Jul. 1, 2008; and, U.S. Pat. No. 7,330,366, entitled "DC-AC Converter" issued to Lee, et al. on Feb. 12, 2008; all of which are incorporated hereinto by reference.

[0067] FIG. **4**B illustrates an electrical arrangement suitable for use in charging a battery. DC IN **40** is buffered by capacitor bank **41** before entering into a step down transformer **43**. Step down transformer **43** reduces the voltage so that the voltage can safely be introduced into battery **44** which is connected to ground **45** at the battery's other pole.

[0068] Those of ordinary skill in the art readily recognize a variety of batteries which will work in this capacity, including, but not limited to those described in: U.S. Pat. No. 7,378,181, entitled "Electric Storage Battery Construction and Manufacture" issued to Skinlo on May 27, 2008; U.S. Pat. No. 7,388,350, entitled "Battery with Electronic Compartment" issued to Wright on Jun. 17, 2008; U.S. Pat. No. 7,397,220, entitled "Connection Member and Battery Pack" issued to Uchida, et al. on Jul. 8, 2008; and, U.S. Pat. No. 7,375,492, entitled "Inductively Charged Battery Pack" issued to Calhoon, et al. on May 20, 2008; all of which are incorporated hereinto by reference.

[0069] In FIG. **4**C, DC IN **40** is fed into an adjustable rheostat **46** which is controlled by the controller so that the DC OUT **47** falls within a specified range.

[0070] FIG. **5** illustrates a conductive line used in the preferred embodiment of the invention.

[0071] This type of conductive line is commonly called poly-wire and consists of multiple interwoven strands of plastic **50**A and **50**B woven into a cord or rope arrangement having intertwined therein exposed metal wires **51**A and **51**B. While this illustration shows two plastic strands and two metal wires, any number of possible combinations is possible.

[0072] The exposed metal wires **51**A and **51**B attract the atmospheric static charge and transmit the charge down to the base unit (not shown).

[0073] FIGS. **6**A and **6**B illustrate an alternative conductive line creating an ionized pathway for the flow of the static charges from the atmosphere.

[0074] This conductive line utilizes a tube **60** having an outer layer **62** of PET Film (Biaxially-oriented polyethylene terephtalate polyester film) which provides exceptionally high tensile strength and is chemically and dimensionally stable. The tube has an ideal diameter of between two and three inches.

[0075] An interior metal coating **61** provides an initial conduit for the flow of static charge. The static charge through the metal forces the tube to expand due to the repulsion experienced by like charges. Further, the flow of electricity causes the interior of the tube **60** to become ionized to provide an additional pathway for the atmospheric static charges to the base unit (not shown).

[0076] Because outer layer **62** provides a gas barrier, the resulting ionization is not dissipated by air currents, thereby providing a highly stable pathway.

[0077] FIG. **7** illustrates the controller of an alternative embodiment and the associated safety devices.

[0078] In this embodiment, controller box **70**, resting on insulating pad **72**, is in communication with the sensors as described above. Using the input from these sensors, when there is flow of electricity through the base unit, warning flashing light **71** is illuminated. To electrically neutralize the mechanism, switch **73** is activated to pass any existing current into the ground **74**.

[0079] FIGS. **8**A and **8**B illustrate two embodiments of enhanced electrical collection leads.

[0080] Referencing FIG. **8**A, enhanced electrical collection lead **82** is a wire mesh which is in electrical communication with conductive line **81** and balloon **80**. Because of the significant amount of metal exposed by enhanced electrical collection lead **82**, more static electricity from the atmosphere is drawn to the collection lead **82**, and then down conductive line **81** to the base unit (not shown).

[0081] Conductive lead **82** is positioned proximate to balloon **80**.

[0082] In FIG. **4**B, poly-wire **83** has enhanced electrical collection leads **84** wrapped therearound. Collection leads **84** have pointed ends **85**A and **85**B which have a propensity to attract more electricity than rounded ends do.

[0083] It is clear from the foregoing that the present invention captures an entirely new source of electrical energy.

What is claimed is:

1. A mechanism to tap an electrical source comprising:

a) a lighter than air balloon;

b) a base unit having a spool of conductive line on a winch motor, one end of said conductive material secured to said lighter than air balloon, said winch motor capable of selectively extending or withdrawing said conductive line from said spool, one end of said conductive line connected to said lighter than air balloon;

c) an insulator electrically isolating said conductive line from ground; and,

d) a conductor having a first end electrically connected to said conductive line and a second end electrically connected to a load.

2. The mechanism to tap an electrical source according to claim **1**, further including a controller, said controller selectively operating said winch motor based upon a voltage level in said conductor.

3. The mechanism to tap an electrical source according to claim **2**,

a) further including an electrical flow sensor monitoring electrical flow through said conductor and generating an electrical flow indicia indicative of said electrical flow in said conductor, said electrical flow indicia communicated to said controller; and,

b) wherein said controller operates said winch motor such that said electrical flow indicia remains within a selected operating range.

4. The mechanism to tap an electrical source according to claim **3**, wherein said selected operating range is established by an operator.

5. The mechanism to tap an electrical source according to claim **4**, further including a warning light activated when said electrical flow indicia is non-zero.

6. The mechanism to tap an electrical source according to claim **3**,

a) further including a lightning sensor generating a lightning presence indicia indicative of lightning within a prescribed range, said presence indicia being communicated to said controller; and,

b) wherein said controller, in response to said lightning presence indicia, operates said winch motor to withdraw substantially all of said conductive line onto said spool.

7. The mechanism to tap an electrical source according to claim **6**, wherein said prescribed range is established by an operator.

8. The mechanism to tap an electrical source according to claim **3**, further including an electrical collection enhancement lead in electrical contact with a first end said conductive material, said electrical collection enhancement lead configured to attract static electricity.

9. The mechanism to tap an electrical source according to claim **8**, wherein said electrical collection enhancement lead is positioned proximate to said lighter than air balloon.

10. The mechanism to tap an electrical source according to claim **9**, wherein said electrical collection enhancement lead includes at least two pointed electrical conductors.

11. The mechanism to tap an electrical source according to claim **1**, wherein said insulator electrically isolates said conductive line from said winch motor.

12. The mechanism to tap an electrical source according to claim **1**, wherein said insulator electrically isolates said base unit from ground.

13. A mechanism comprising:

a) an airborne aircraft tethered by a conductive line secured to a winch capable of extending or withdrawing said conductive line from a spool, thereby adjusting an altitude of the airborne aircraft;

b) an insulator electrically isolating said conductive line from ground; and,

c) a conductor having a first end electrically connected to said conductive line and a second end electrically connected to a load.

14. The mechanism according to claim **13**, further including a controller, said controller selectively operating said winch motor based upon a voltage level in said conductor.

15. The mechanism to tap an electrical source according to claim **14**,

a) further including a lightning sensor communicating with said controller; and,

b) wherein said controller, in response to selected signals from said lightning sensor withdraws substantially all of said conductive line.

16. A mechanism to tap an electrical source comprising:

a) a lighter than air balloon;

b) a base unit having a spool of conductive line on a winch motor, one end of said conductive material secured to said balloon, said winch motor capable of adjusting an altitude of said lighter than air balloon by selectively extending or withdrawing said conductive line from said spool;

c) an insulator electrically isolating said conductive line from ground; and,

d) a conductor having a first end electrically connected to said conductive line and a second end electrically connected to a load;

e) a sensor array having,

   1) an electrical flow sensor monitoring electrical flow through said conductor, and,

   2) a lightning sensor monitoring existence of proximate lightning; and,

f) a controller responsive to signals from said sensor array to selectively operate said winch motor.

17. The mechanism to tap an electrical source according to claim **16**,

a) further including a warning light; and,

b) wherein said controller activates said warning light when said electrical flow in said conductor is non-zero.

18. The mechanism to tap an electrical source according to claim **17**, further including an electrical collection enhancement lead in electrical contact with said conductive material, said electrical collection enhancement lead configured to attract static electricity and positioned proximate to said lighter than air balloon.

(57) **ABSTRACT**

An airborne vehicle having a wing-body which defines a wing-body axis and appears substantially annular when viewed along the wing-body axis, the interior of the annulus defining a duct which is open at both ends. A propulsion system is provided comprising one or more pairs of propulsion devices, each pair comprising a first propulsion device mounted to the wing-body and positioned on a first side of a plane including the wing-body axis, and a second propulsion device mounted to the wing-body and positioned on a second side of the plane including the wing-body axis. A direction of thrust of the first propulsion device can be adjusted independently of the direction of thrust of the second propulsion device and/or a magnitude of thrust of the first propulsion device can be adjusted independently of the magnitude of thrust of the second propulsion device. In certain embodiments the wing-body appears swept forward when viewed from a first viewing angle, and swept backward when viewed from a second viewing position at right angles to the first viewing angle.

ANNULAR AIRBORNE VEHICLE

[0001] The present invention relates to an annular airborne vehicle—that is, a vehicle having an outer wing-body which defines a wing-body axis and appears substantially annular when viewed along the wing-body axis, the interior of the annulus defining a duct which is open at both ends.

[0002] It is well understood that aircraft should be designed for minimal drag and mass characteristics, while maximising lift and aeroelastic characteristics so that fundamental aircraft design parameters may be adapted to achieve specific goals including better lift to drag ratios, better fuel efficiency, longer endurance and higher payload capacities, for example.

[0003] These fundamental design goals remain true whether the aircraft might be a miniature unmanned air vehicle (UAV), or a glider, or a passenger aircraft, or indeed a large transport aircraft.

[0004] It is an objective in many UAV applications to provide means for short take off and landing (STOL) or vertical take off and landing (VTOL), so that devices may be deployed and recovered without difficulty when runways may not be available. It is also desirable for UAVs to include means to hover, where surveillance, localisation, or communications activities may be required with little or no aircraft motion relative to the ground. Under such scenarios it is also desirable that the UAV should be capable of transition into an efficient forward flight phase, and vice versa, so that vehicle endurance would not necessarily be compromised by flight inefficiencies during VTOL, STOL, or hover phases. Under some circumstances it is advantageous to deploy such UAVs not only from ground but also from aircraft which may already be in flight, or land vehicles which may themselves be in motion, and therefore such UAVs would require special capabilities in order to withstand the demanding conditions imposed by such deployment envelopes.

[0005] Large UAVs are used in high altitude, long endurance scenarios where reconnaissance, or surveillance or imaging or communications functions may be required in order to achieve mission goals. Under such scenarios the endurance characteristics of the UAV become more important than take off or landing aspects, where lift to drag ratios must be high, mass must be low, and strength to weight ratios must also be high. It follows from aerodynamic principles that induced drag may be minimised by increasing the aspect ratio (AR) of the wing, where:

$$AR=B^2/S$$

(B=span; S=projected planform area)

[0006] which produces long slender wings where maximal efficiency must be balanced with aeroelastic constraints where wing structures must also survive other stresses induced during severe weather or take off or landing. Therefore such UAVs require improved vehicle forms in order to deliver better performance in terms of endurance, or range, or fuel efficiency, or payload capacity.

[0007] Therefore it is an object of this invention to disclose a common annular air vehicle form that may be utilised efficiently across a variety of UAV applications including those based upon miniature, agile vehicles, and large high altitude long endurance vehicles, and gliders.

[0008] It is also another object of this invention to disclose a common annular air vehicle form that may be utilised efficiently across a variety of manned aircraft applications including those based upon glider, light transit, heavy transit and passenger aircraft.

[0009] A first aspect of the present invention provides an airborne vehicle having a wing-body which defines a wing-body axis and appears substantially annular when viewed along the wing-body axis, the interior of the annulus defining a duct which is open at both ends; and a propulsion system comprising one or more pairs of propulsion devices, each pair comprising a first propulsion device mounted to the wing-body and positioned on a first side of a plane including the wing-body axis, and a second propulsion device which is mounted to the wing-body, positioned on a second side of the plane including the wing-body axis, and operable independently of the first propulsion device.

[0010] Preferably a direction of thrust of the first propulsion device can be adjusted independently of the direction of thrust of the second propulsion device, for instance by rotating the propulsion device. Alternatively each propulsion device comprises a thrust generator and a plurality of ducts arranged to receive propulsion gas from the thrust generator, and the direction of thrust of each propulsion device can be adjusted independently of the direction of thrust of the other propulsion device by adjusting the flow of propulsion gas in the ducts. In this case typically each duct is contained within the wing-body and at least some of the ducts have an inlet and an outlet in the wing-body.

[0011] In certain embodiments a thrust vector of each propulsion device can be adjusted between a first configuration in which the thrust vectors are co-directed and a second configuration in which the thrust vectors are contra-directed.

[0012] In one embodiment of the first aspect of the invention a magnitude of thrust of the first propulsion device can be adjusted independently of the magnitude of thrust of the second propulsion device, but not the direction of thrust.

[0013] Thus in general terms the propulsion devices are operable independently in the sense that either the direction of thrust of the first propulsion device can be adjusted independently of the direction of thrust of the second propulsion device; or a magnitude of thrust of the first propulsion device can be adjusted independently of the magnitude of thrust of the second propulsion device; or both.

[0014] Preferably a controller device is provided which is configured to independently operate the propulsion devices by issuing respective control signals to the propulsion devices.

[0015] A second aspect of the invention provides an airborne vehicle having a wing-body which defines a wing-body axis and appears substantially annular when viewed along the wing-body axis, the interior of the annulus defining a duct which is open at both ends, wherein the wing-body appears swept forward when viewed from a first viewing angle, and swept backward when viewed from a second viewing position at right angles to the first viewing angle.

[0016] In certain embodiments of the invention, the double-swept configuration of the second aspect of the invention provides several advantages:

- **[0017]** it enables the center of gravity of the annular vehicle to be more easily separated from its center of pressure, and therefore provides for better static and dynamic margins in pitch stability;
- **[0018]** aeroelastic forces which would otherwise subject conventional planar forwardly swept wings to excessive

tensile or flutter loads are effectively braced and dampened by the resilient annular structure of the wing-body;

[0019] the element of forward sweep makes the vehicle more tolerant of relatively high angles of attack, with lower susceptibility to stall, which is important when executing landings, take-off or other manoeuvres;

[0020] the element of forward sweep improves lift over drag ratios under some circumstances.

[0021] Preferably the wing-body has a leading edge with two or more noses, and a trailing edge with two or more tails which may be rotationally offset in relation to the noses (for instance by 90 degrees).

[0022] Typically at least part of the leading and/or trailing edge of the wing-body follows a substantially helical curve.

[0023] A third aspect of the invention provides an airborne vehicle having a wing-body which defines a wing-body axis and appears substantially annular when viewed along the wing-body axis, the interior of the annulus defining a duct which is open at both ends, wherein the wing-body carries at least one rudder on its left side and at least one rudder its right side.

[0024] In some embodiments the wing body carries two or more rudders on its left side and two or more rudders on its right side, and the wing-body is formed with a slot between each adjacent pair of rudders.

[0025] Preferably the wing-body has a projected planform area S, and a maximum outer diameter B normal to the wing-body axis, and wherein the ratio B^2/S is greater than 0.5. The relatively large diameter wing-body enables an array of two or more sensors to be well spaced apart on the wing-body, providing a large sensor baseline. In this way the effective acuity of the sensor array increases in proportion to the length of the sensor baseline. Also, the relatively high ratio B^2/S gives a high ratio of lift over drag, enabling the vehicle to be operated efficiently as a glider.

[0026] The duct may be fully closed along all or part of its length, or partially open with a slot running along its length. The duct may also include slots or ports to assist or modify its aerodynamic performance under certain performance conditions.

[0027] Various embodiments of the invention will now be described by way of example with reference to the accompanying drawings, in which:

[0028] FIG. **1***a* is a front view of a first propelled vehicle;

[0029] FIG. **1***b* is a cross-section of the right-hand side of the vehicle taken along the wing-body axis and along a line A-A in FIG. **1**;

[0030] FIG. **1***c* is a cross-section of the right-hand side of a second propelled vehicle, where its propellers are located within the forward half of the duct;

[0031] FIG. **2***a* is a cross-section of the right-hand side of a third propelled vehicle taken along the wing-body axis and along a line B-B in FIG. **2***b*, where its propellers are located within the rearward half of the duct;

[0032] FIG. **2***b* is a plan view of the third propelled vehicle;

[0033] FIG. **2***c* is a cross-section of the right-hand side of a fourth propelled vehicle taken along the wing-body axis and along a line C-C in FIG. **2***d*, where its propellers are located within the forward half of the duct;

[0034] FIG. **2***d* is a plan view of the fourth propelled vehicle;

[0035] FIG. **3***a* is a front view of the fourth propelled vehicle with its propellers in an up thrust configuration;

[0036] FIG. **3***b* is a cross-section of the right-hand side of the fourth propelled vehicle taken along the wing-body axis and along a line D-D in FIG. **3***a;*

[0037] FIG. **3***c* is a front view of the fourth propelled vehicle with its propellers in a contra-directed spin thrust configuration;

[0038] FIG. **3***d* is a cross-section of the right-hand side of the fourth propelled vehicle taken along the wing-body axis and along a line D-D in FIG. **3***c;*

[0039] FIG. **4***a* is a front view of a fifth propelled vehicle with its propellers in a forward thrust configuration and located behind the rearward half of the duct;

[0040] FIG. **4***b* is a cross-section of the right-hand side of the fifth propelled vehicle taken along the wing-body axis and along a line E-E in FIG. **4***a;*

[0041] FIG. **4***c* is a cross-section plan view of the fifth propelled vehicle taken along a line F-F in FIG. **4***a;*

[0042] FIG. **5***a* is a front view of a sixth propelled vehicle with its propellers mounted conformally within the annular wing body;

[0043] FIG. **5***b* is a cross-section of the right-hand side of the sixth propelled vehicle taken along a line G-G in FIG. **5***a;*

[0044] FIG. **5***c* is a rear view of the vehicle of FIG. **5***a;*

[0045] FIG. **5***d* is an underside view of the vehicle of FIG. **5***a;*

[0046] FIG. **6***a* is a front view of a glider;

[0047] FIG. **6***b* is a cross-section of the right-hand side of the glider taken along the wing-body axis and along a line H-H in FIG. **6***a;*

[0048] FIG. **6***c* is a plan view of the glider;

[0049] FIG. **7***a* is a front view of a seventh propelled vehicle;

[0050] FIG. **7***b* is a side view of the vehicle of FIG. **7***a;* and

[0051] FIG. **7***c* is a plan view of the vehicle of FIG. **7***a*.

[0052] Referring to FIGS. **1***a* and **1***b*, an airborne vehicle **1** has an outer wing-body **2** which is evolved from a laminar flow aerofoil profile (shown in FIG. **1***b*) as a body of revolution around a wing-body axis **3**. Thus the outer wing-body **2** appears annular when viewed along the wing-body axis as shown in FIG. **1***a*. An inner wall **4** of the annulus defines a duct **5** which is open fore and aft so that air flows through the duct as the vehicle moves through the air, generating aerodynamic lift by differential fluid flow across upper and lower aerofoil surfaces, which in this example arises whenever the axis of the annulus maintains an angle of incidence to its trajectory.

[0053] As shown in FIG. **1***b*, the aerofoil profile tapers outwardly gradually from a narrow nose end **6** to a widest point **7**, then tapers inwardly more rapidly to a tail end **8**. In this particular embodiment the widest point **7** is positioned approximately two-thirds of the distance between the nose and tail ends. The particular aerofoil section as described has symmetrical upper and lower surfaces which in this example provides for low minimum drag under cruising conditions, and may be modified in variants of this and other vehicles so as to modify the coefficients of lift, drag and pitch moment to suit the particular mission envelope and associated fluid flow regime as determined by the relevant range of Reynolds numbers.

[0054] A pair of propulsors **9**, **10** are mounted symmetrically on opposite sides of a vertical plane containing the wing-body axis **3**. In this particular embodiment the propulsors are shown as ducted electric fan motors comprising propellers (or impellers) **11**, **12** which are mounted on L-shaped support shafts **13**, **14** which in turn are mounted to the wing-body in line with the widest point **7** as shown in FIG. **1***b*. The propellers are mounted within shrouds **15**, **16** in such a way that their efficiency is increased within a proportion of the motor operating envelope. Each I,-shaped shaft is pivotally mounted to the wing-body so that it can rotate independently of the other shaft by 360 degrees relative to the wing-body about an axis parallel to the pitch axis of the vehicle, thus providing thrust-vectored propulsion. Both the shroud and L-shaped shaft have an aerofoil section using a ratio between chord length and height similar to that described for the outer wing-body, where the optimal relationship between height and chord is once again determined by the relative fluid flow regime as described by the relevant Reynolds number for these elements. Thus for example the propulsors **9**, **10** can be rotated between the co-directed configuration shown in FIGS. **1***a* and **1***b*, in which they provide a thrust force to propel the vehicle forward and along the wing-body axis, to a contra-directed configuration (not shown) in which they cause the vehicle to roll continuously around the wing-body axis.

[0055] The vehicle uses four independently operable motors (not shown) within its propulsion system: two brushless DC electric motors to drive the propellers, and two DC electric brushless motors to drive the L-shaped support shafts upon which the propeller motors are mounted, where a mechanical worm drive gear reduction mechanism is used to transfer drive and loads between the motor and the L-shaped shafts. Alternative motor types such as stepper motors may be used for the latter scheme, so long as operating loads are consistent with the rating of the motors. Similarly alternative motor types may be adopted for the propulsors, including internal combustion, gas turbine or solid propellant motors.

[0056] The thrust-vectored propulsors provide the means for motion along the wing-body axis, either forward or in reverse, and spin or roll around the wing-body axis, and pitch or yaw about the vehicle's centre of gravity (CofG), which in this embodiment is located below the wing-body axis, above the lower annulus section, within a vertical plane that contains the wing-body axis, and approximately at 15 to 23% of the chord length when measured from the nose. As described earlier it is clear that the two propulsors may be contra-directed in order to induce vehicle roll. The two propulsors may also be co-directed. For instance when both are directed down so that their thrust vectors lies above the CofG, then the vehicle will pitch nose down. Similarly when the two propulsors are directed up so that their thrust vector lies below the CofG, then the vehicle will pitch nose up. It is also clear that varying degrees of propulsor pitch in relation to the vehicle and each other may be used to achieve vehicle pitch, roll and yaw. Yaw may also be induced by differential thrust application when differential propeller revolution rates are adopted. Thus it can be seen that the vehicle is able to dive, turn, roll and climb under its own autonomous control, since the vehicle also includes a controller device that includes the means to measure linear accelerations in three orthogonal axes, and angular accelerations in three orthogonal axes, and processing methods to calculate the control demands that would be delivered to the propulsion system.

[0057] Thus the direction of thrust of the propulsor **9** can be adjusted by the controller device independently of the direction of thrust of the propulsor **10** by issuing control signals to the electric motors which drive the L-shaped support shafts. Also, the magnitude of thrust of the propulsor **9** can be adjusted by the controller device independently of the magnitude of thrust of the propulsor **10** by issuing control signals to the electric motors which drive the the propellers.

[0058] The vehicle has a high degree of manoeuvrability, since its thrust vectored propulsion may be arranged for high turn rates under dynamic control. It is also clear that the vehicle has a high degree of stability. In the first instance when motion is along the axis of the wing-body then relatively high speeds may be achieved with contra-rotating propellers that cancel induced torque, while contra-directed propulsors provide for further roll stability. In the second instance when spin motion around the wing-body axis is induced, then angular momentum is increased and once again the stability of the vehicle is increased, where this may be measured as a reduction in vehicle attitude or position errors when subject to external forces.

[0059] A significant advantage offered by this propulsion system is the provision of effective attitude control at slow speeds, when alternative control surfaces would be much less effective. It follows therefore that large thrust vector demands may be used effectively at slow speeds, and during launch or recovery, or take off and landing, while low thrust vector demands would satisfy the majority of performance envelope demands when traveling at speed. Another significant advantage of this arrangement is the relative ease with which the vehicle may transition from launch to forward transit, or to hover, or VTOL/STOL, and vice versa. A further significant advantage of this arrangement is the low drag characteristic of the annular wing-body, which preferentially allows for high speed transit in normal forward flight.

[0060] The nose of the vehicle carries a pair of video cameras **17**,**18** for collision avoidance and imaging applications. The relatively large diameter of the wing-body enables the cameras to be well spaced apart, thus providing a long stereoscopic baseline that provides for accurate range estimation by measurement of parallax between objects located within both camera fields of view. An ultrasonic transmitter **20** and two receivers **21**, **22** are provided for acoustic imaging and sensing. Again, the wide baseline is an advantage since localization accuracy will be improved by differential time of flight processing between the separated receivers. The outer wing-body **2** contains an interior space which can be seen in FIG. **1***a*. This outer wing-body is preferentially manufactured from a stiff composite material using glass or carbon fibre filaments laminated alternately between layers of epoxy resin. Alternatively a cheaper, less resilient wing-body may be moulded from a suitable hard polymer such as polyurethane or high density polyethylene. Under certain conditions where mass reduction is paramount then the outer wing-body skin may be formed instead from a tough polymer film such as mylar. It is also possible to manufacture the outer wing-body from aluminium, should the wing-body be pressurised. The interior space may be pressurized, and houses a pair of battery packs **21**, **22**, a pair of tail sensors **23**, **24**, and four toroidal vessels **25**-**28** spaced apart along the wing-body axis. The vessels may contain the vehicle electronics, some propulsion sub-system elements and other items, and are joined by axial or tri-lateral struts (not shown) which would share the construction methods adopted for the toroidal vessels. In this particular embodiment the toroidal vessels are preferentially manufactured from stiff composites using either glass or carbon fibre filaments wound helically around the toroid and alternately laminated between layers of epoxy resin. Alternatively the toroidal vessels may be manufactured from a suitable grade of metal such as aluminium, stainless or galvanized steel, or titanium. The toroidal and annular structures disclosed herein are designed to provide for superior aeroelastic resilience around the wing-body so that mass may effectively and safely be reduced without risk of major stress loading or concentration at any section of the annulus.

[0061] The aspect ratio (AR) of the annular wing-body is defined as follows:

$$AR=2B^2/S$$

[0062] where B is the span of the wing-body (defined by the maximum outer diameter of the wing-body) and where S is the projected planform area of the wing-body.

[0063] In the vehicle of FIG. **1***a,* the AR is approximately 2, although this number may be modified in other embodiments where the application may demand other ratios. It is evident that the vehicle form may be adjusted by simple variation of its toroidal diameter to reflect narrow vehicles where aspect ratio is low, or to reflect broad vehicles where aspect ratio is high. In either case specific advantages may be gained under certain circumstances, since relatively high coefficients of lift may be achieved using a toroidal form with low aspect ratio, while optimal glide slope ratios, or equivalent ratios of lift over drag may be achieved using a toroidal form with high aspect ratio.

[0064] In the embodiment of FIGS. **1***a* and **1***b,* the propulsion devices are mounted towards the tail of the vehicle—that is towards the right-hand side of FIG. **1***b.* In the second embodiment shown in FIG. **1***c* the propulsion devices are mounted towards the nose of the vehicle—that is towards the left-hand side of FIG. **1***c.* The front view of the vehicle of FIG. **1***c* is identical to that of the vehicle of FIG. **1***b.*

[0065] A swept-wing vehicle is shown in FIGS. **2***a* and **2***b.* The front view of the vehicle of FIGS. **2***a* and **2***b* is identical to that of the vehicle of FIG. **1***b.*

[0066] The leading edge **30** of the wing-body of the vehicle describes a form of helical curve around one quadrant of the circumference of the wing body, where such a helix subtends an angle +θ with a vertical line $\mathbf{3}_y$ perpendicular to the wing-body axis **3**, when viewed in elevation as shown in FIG. **2***a.* This helical curve is used identically around the third quadrant of the circumference of the wing-body leading edge, while its mirror image is used to form the second and third quadrants of the leading edge. The four helical elements are joined, so that the leading edge forms a closed double chevron sweep around the forward circumference of the wing-body. Within this particular embodiment, the trailing edge forms an identical closed double chevron sweep which is translated along the axis **3** by the chord length of the aerofoil. In other embodiments the relationship between the leading and trailing double chevron sweeps may be modified, for example to vary the relationship between orthogonal lift and rudder stabilization surfaces.

[0067] Similarly the trailing edge **31** of the wing-body of the vehicle subtends a positive angle (not labeled) with the line $\mathbf{3}_y$. Thus, because the mid-chord line of the wing-body (that is, a line at the mid-point between the leading and trailing edges) subtends a positive angle with the line $\mathbf{3}_y$ on both the upper and lower sides of the wing-body, the wing-body appears swept backward when viewed in elevation. In contrast, the leading edge **30** of the wing-body of the vehicle subtends an angle −θ with a horizontal line $\mathbf{3}_x$ perpendicular to the wing-body axis **3**, when viewed in plan as shown in FIG. **2***b.* Similarly the trailing edge **31** of the wing-body of the vehicle subtends a negative angle (not labeled) with the line $\mathbf{3}_x$. Thus, because the mid-chord line of the wing-body (that is, a line at the mid-point between the leading and trailing edges) subtends a negative angle with the line $\mathbf{3}_x$ on both the left and right-hand sides of the wing body, the wing-body appears swept forward when viewed in plan.

[0068] The sweep angle δ is described in FIG. **7***c* (and also labelled with numeral **69**) under an alternative embodiment and may vary between 0 to 60°, and 0 to −60°, where δ is defined as the angle subtended by the helix H_{xy} (i.e, the mid-chord line of the wing-body) and any plane which lies normal to the axis of the annular wing-body, and where H_{xy} is transcribed by the mid-chord line around the annular wing-body, and where δ is constrained by the axial displacement t**1** between the two chords whose tangential planes are vertical (i.e, left and right sides) in relation to the chords whose tangential planes are horizontal (i.e top and bottom sections). In this example and other embodiments the mean value of δ may be determined within each of four quadrants bounded by two orthogonal planes that coincide with the wing body axis **3**, at which boundaries δ becomes zero. The axial displacement t**1** is greater than or equal to 0.1 times the chord of the annulus. These relationships are described again in FIG. **7***c.*

[0069] In the embodiment of FIGS. **2***a* and **2***b,* the propulsion devices are mounted towards the tail of the vehicle—that is towards the right-hand side of FIGS. **2***a* and **2***b.* In the embodiment shown in FIGS. **2***c* and **2***d,* the propulsion devices are mounted towards the nose of the vehicle—that is towards the left-hand side of FIGS. **2***c* and **2***d.* The front view of the vehicle of FIGS. **2***c* and **2***d* is identical to that of the vehicle of FIG. **1***b.*

[0070] FIGS. **3***a* and **3***b* illustrate the vehicle of FIGS. **2***c* and **2***d* with its propellers in an up thrust configuration, and FIGS. **3***c* and **3***d* illustrate the vehicle of FIGS. **2***c* and **2***d* with its propellers in a contra-directed spin thrust configuration.

[0071] FIGS. **4***a*-**4***c* show a variant of the vehicle of FIGS. **2***a* and **2***b.* Whereas the wing-body in the vehicle of FIGS. **2***a* and **2***b* is swept forward when viewed in plan, the wing-body in FIGS. **4***a*-**4***c* is swept backward when viewed in plan. In this configuration the static and dynamic pitch stability margins are reduced by comparison with the wing-body scheme described in FIG. **2**, however the propulsors have greater degrees of freedom in thrust vector control with lower interference to lifting surface fluid flows. As a consequence this scheme offers further improvements in vehicle agility.

[0072] FIG. **5***a* is a front view of a sixth propelled vehicle, employing a conformal propulsion system. A starboard propeller (or impeller) **40** is mounted in the inlet port **44** of a starboard main duct **42** which runs along the starboard side of the hull to a main outlet port **45**, and a port propeller **41** (or impeller) is mounted in the inlet port of a port main duct **43** which runs along the port side of the hull to a main outlet port (not shown).

[0073] The ducting network of the propulsion system is symmetrical, so only the starboard elements will be described in detail with reference to FIG. **5***b.* The starboard main duct **42** is coupled to a forward duct **46** at an inlet **47**, and to a rear duct **48** at an inlet **49**. The forward duct **46** has port and starboard underside outlet ports **52**, **50** in the underside of the hull, and the rear duct **48** has port and starboard underside outlet ports **53**, **51** in the underside of the hull.

[0074] The port main duct **43** is also coupled to the ducts **46**,**48** via inlets (not shown) on the port side of the vehicle, similar to the inlets **47**,**49**.

[0075] Note that all of the ducts described above are contained within the annular wing-body.

[0076] Valves (such as butterfly valves or sliding plate valves) are provided in the inlets **47**, **49** (and the equivalent inlets on the port side of the vehicle), in the underside outlet ports **50-53**, in the main outlet port **45** (and the equivalent main outlet port on the port side of the vehicle), and in the forward and rear ducts **46**, **48** between the port and starboard underside outlet ports. The valves may be opened and closed digitally by pulse width modulation control.

[0077] The valves can be operated independently to adjust the flow of propulsion gas in the ducts, and thus adjust the magnitude and direction of the thrust generated by the port and starboard propulsion systems. For example forward thrust can be achieved by closing the valves in the inlets **47**, **49** (and the equivalent inlets on the port side of the vehicle), and opening the valves in the port and starboard main outlet ports. VTOL, STOL, or hover phases can be achieved by closing (fully or partially) the valves in the port and starboard main outlet ports, and opening all other valves.

[0078] The underside outlet ports **50-53** are arranged to enclose a vertical axis that locates the centre of gravity (CofG) of the vehicle within a horizontal frame of reference. Therefore during VTOL, STOL or hover phases the propellers, motors, ducts, and valves may be controlled by a suitable device so that thrust may be adjusted between the four ports **50-53** in such a way that vehicle attitude and resultant vehicle accelerations and velocities may be precisely controlled.

[0079] This controller device is described above for earlier variants of this annular wing-body. Once again the embodiment is particularly described with ducted electric fan motors, although these may be replaced by suitable alternative motors including internal combustion, gas turbine, or solid propellant motors.

[0080] A glider vehicle is shown in FIGS. **6***a-c*. The wing-body of the vehicle has an annular construction as shown in FIG. **6***a*, and adopts a forwardly swept shape similar to the wing-body of FIGS. **2***a* and **2***b*. The wing-body uses similar construction, and houses various sensors, battery packs, and toroidal vessels in common with the vehicles shown in FIGS. **1-4**.

[0081] Because the glider has no propulsion devices, it has a fully conformal outer shape with no superstructure either inside the duct or projecting from the exterior of the vehicle, other than its two elevators **32**, **33** and two rudders **30**, **31** which are conformally and orthogonally mounted around the rear of the wing-body. The elevators and rudders are secured to the wing-body by linkage mechanisms that provide for rotation within arcs of ±30°. The elevators and rudders are controlled by worm drive mechanisms as disclosed for propulsor controls in FIGS. **1** to **5**.

[0082] FIGS. **7***a*-**7***c* show a propelled vehicle according to a further embodiment of the invention. As described for vehicles disclosed in FIGS. **2** to **6**, this particular embodiment of the annular wing-body also includes wing sweep, and in particular a symmetrical double chevron sweep as explained for the vehicles described in FIG. **2**, only in this embodiment the sweep angle δ **69** is approximately 21 degrees.

[0083] The vehicle has a twin propulsion system **70**, **71** similar to that shown in FIGS. **2***a*/**2***b* although in this particular embodiment the motors are mounted on the lower half of the annulus. Also, in contrast to the propulsion system of FIGS. **2***a*/**2***b* (in which the direction and magnitude of thrust of each propulsion device can be adjusted independently of the direction and magnitude of thrust of the other propulsion device) vector control actuation elements are not included in the embodiment of FIGS. **7***a*-**7***c* so in this case only the magnitude of thrust of each propulsion device can be adjusted independently of the magnitude of thrust of the other propulsion device, and not the direction of thrust (other than by switching between forward and reverse modes). Note also that in a further embodiment (not shown) the propulsion system of FIGS. **2***a*/**2***b* may be fitted to the vehicle of FIGS. **7***a*-**7***c*.

[0084] The position of the motors around the annulus may be adjusted symmetrically about the vertical plane that contains the wing-body axis, where absolute thrust vectors would need to be aligned to best fit the range of flight regimes intended. Elevators **74**, **75** and ailerons **72**, **73** are included on the upper cambered wing-body section, while elevators **78**, **79** and ailerons **76**, **77** are included on the lower cambered wing-body section, and rudders **80** to **82** are included on the left side of the wing-body, while rudders **83** to **85** are included on the right side of the wing-body. The form of this annular vehicle is particularly suited to large, high endurance platforms which seek to minimize mass and maximize operational efficiency and where agility concerns would not be so prevalent. Once again the annular wing-body form seeks to maximize a broad range of performance criteria including resilience to aeroelastic loading which become more dominant when aspect ratios become large.

[0085] In contrast with the circular annulus shown in FIG. **1***a*, the annulus is wider than it is tall, as shown in the front view of FIG. **7***a*. In this embodiment the relationship between span B and chord is 8 to 1, while span B to wing-body height H is 5 to 1. The aspect ratio of this embodiment is derived from:

$$AR=2B^2/S$$

[0086] Where AR=16

[0087] This particular aspect ratio is suited to long endurance operations where efficient soaring will be required.

[0088] The wing-body is arranged as four cambered sections **94** to **97** joined by four curved elements **90** to **93** that provide both for structural bracing and conformal housing of twin motors, fuel, batteries, undercarriage, control systems, stowage bays and payload items. The construction of the wing-body follows the methods and materials described for the earlier wing-bodies of FIGS. **1** to **6**, where composite technologies would be used extensively within its structures. Similarly the motors may be based upon ducted electric fan, or internal combustion, or gas turbine technologies in either of push or pull configuration, augmented by hybrid energy sources including photovoltaic and fuel cell technologies.

[0089] The wing-body vehicle has three undercarriage elements **40** for providing stability during take-off and landing operations. Two elevator and two aileron elements **72** to **79** are included on each of the upper and lower sections of the annular wing-body, where the linkage mechanism that secures these elements is similar to that disclosed for the vehicle form described in FIG. **6***b*, while its control mechanism uses a worm drive as disclosed for vehicle forms disclosed in FIGS. **1** to **6**. A plurality of rudder elements **80** to **85** are arranged at either vertical side of the annulus, using a linkage mechanism similar again to that described in FIG. **6***b*, and a control mechanism based again upon a worm drive as disclosed for vehicle forms described in FIGS. **1** to **6**, together with flared slots **86** to **89** between each adjacent pair of rudders which provide for longitudinal separation τ_2 between each rudder element where the ratio S_r between the separation distance t**2** and the mid-chord length of the rudder element C_{mr} may vary between 0.5 and 5, such that:

$$S_r = t2/C_{mr}$$

[0090] and where the vertical height H_{sr} subtended by the slots may vary between 0.3 and 0.8 times the height H of the annulus. Each rudder element incorporates an appropriate aerofoil to ensure smooth aerodynamic flow along their discrete surfaces, where the precise aerofoil shape would be similar to that adopted for the other sections of the annular wing body, with adjustments as might be necessary for the variation in Reynolds number associated with rudder chord reduction.

[0091] In this particular embodiment three rudder elements **80** to **82** and **83** to **85** are shown on each of left and right sides of the annular wing-body, and two flared slots **86**, **87** and **88**, **89** are also shown between the rudder elements on each of left and right sides. Each rudder houses a secure linkage that bonds with upper and lower wing-body sections to ensure structural integrity, and to allow for rotation within a prescribed arc about a vertical axis, where the arc would normally be constrained to less than ±30°.

[0092] In this embodiment of the annular wing-body the combination of annulus, slots and multiple rudders serve to minimise induced drag, parasitic drag, mass and cross-flow effects for the whole of the annual wing-body vehicle while providing for stability and control in yaw. The double chevron sweep configuration also improves the soaring capability of the annular wing-body, where lift over drag ratios are increased by the effective forward sweep of upper and lower cambered lifting sections of the annular wing-body.

[0093] The high rotational symmetry of many of the wing-body shapes (as viewed along the wing-body axis) described herein gives other advantages where the vehicle is to be operated in a continuous or transient roll mode. However, the invention also covers alternative embodiments of the invention (not shown) including:

- **[0094]** embodiments in which the duct is divided into two or more separate ducts by suitable partitions
- **[0095]** embodiments in which the outer wing-body itself defines two or more separate ducts
- **[0096]** embodiments in which the outer wing-body is evolved from an aerofoil as a body of revolution around the wing-body axis by an angle less than 360 degrees. In this case, instead of being closed, the duct will be partially open with a slot running along its length. By making the angle greater than 180 degrees, and preferably close to 360 degrees, the wing-body will remain substantially annular so as to provide aerodynamic lift at any angle of roll.

[0097] The annular air vehicles described above achieve significant improvements in overall performance when measured across a broad range of whole vehicle criteria including lift to drag ratios, agility, stability, endurance, launch and recovery, take off or landing, power to weight ratios, fuel efficiency and resilience to aeroelastic loading.

1. An airborne vehicle having a wing-body which defines a wing-body axis and appears substantially annular when viewed along the wing-body axis, the interior of the annulus defining a duct which is open at both ends; and a propulsion system comprising one or more pairs of propulsion devices, each pair comprising a first propulsion device mounted to the wing-body and positioned on a first side of a plane including the wing-body axis, and a second propulsion device which is mounted to the wing-body, positioned on a second side of the plane including the wing-body axis, and operable independently of the first propulsion device, wherein a direction of thrust of the first propulsion device can be adjusted independently of the direction of thrust of the second propulsion device.

2. The vehicle of claim **1** wherein the direction of thrust of the first propulsion device can be adjusted independently of the direction of thrust of the second propulsion device by rotating the propulsion device.

3. The vehicle of claim **1** wherein each propulsion device comprises a thrust generator and a plurality of ducts arranged to receive propulsion gas from thrust generator, and wherein the direction of thrust of the first propulsion device can be adjusted independently of the direction of thrust of the second propulsion device by adjusting the flow of propulsion gas in the ducts.

4. The vehicle of claim **3** wherein each duct is contained within the wing-body.

5. The vehicle of claim **1** wherein a thrust vector of each propulsion device can be adjusted between a first configuration in which the thrust vectors are co-directed and a second configuration in which the thrust vectors are contra-directed.

6. The vehicle of claim **1** wherein at least part of the wing-body is swept with respect to the wing-body axis.

7. The vehicle of claim **6** wherein the wing-body appears swept forward when viewed from a first viewing angle, and swept backward when viewed from a second viewing position at right angles to the first viewing angle.

8. The vehicle of claim **7** wherein the outer wing-body appears swept forward when viewed in elevation, and swept backward when viewed in plan.

9. The vehicle of claim **1** wherein the first propulsion device is positioned on a first side of a vertical plane including the wing-body axis, and the second propulsion device is positioned on a second side of the vertical plane including the wing-body axis.

10. The vehicle of claim **1** further comprising a controller device which is configured to independently operate the propulsion devices by issuing respective control signals to the propulsion devices.

11. An airborne vehicle having a wing-body which defines a wing-body axis and appears substantially annular when viewed along the wing-body axis, the interior of the annulus defining a duct which is open at both ends, wherein the wing-body appears swept forward when viewed from a first viewing angle, and swept backward when viewed from a second viewing angle at right angles to the first viewing angle.

12. The vehicle of claim **11** wherein the wing-body appears swept forward when viewed in plan, and swept backward when viewed in elevation.

13. The vehicle of claim **11** wherein the wing-body has a leading edge with two or more noses, and a trailing edge with two or more tails.

14. The vehicle of claim **13** wherein the noses are rotationally offset in relation to the tails.

15. The vehicle of claim **11** wherein at least part of the leading and/or trailing edge of the wing-body follows a substantially helical curve.

16. An airborne vehicle having a wing-body which defines a wing-body axis and appears substantially annular when viewed along the wing-body axis, the interior of the annulus defining a duct which is open at both ends, wherein the wing-body carries at least one rudder on its left side and at least one rudder its right side.

17. The vehicle of claim **16** wherein the wing body carries two or more rudders on its left side and two or more rudders on its right side.

18. The vehicle of claim **17** wherein the wing-body is formed with a slot between each adjacent pair of rudders.

19. The vehicle of claim **1** wherein the wing-body has a projected planform area S, and a maximum outer diameter B normal to the wing-body axis, and wherein the ratio B2/S is greater than 0.5.

20. The vehicle of claim **1** further comprising three or more undercarriage elements for providing stability during take-off and landing operations.

21. The vehicle of claim **1** further comprising an energy source housed at least partially inside the outer wing-body.

(57) **ABSTRACT**

This invention relates to an improvement in systems, methods and apparati for handling and processing information, energy and matter by making use of potentials of new technologies, science and industrial art, principally in cymatics, quantum field theory and psychoenergetic science. It comprises a system of methods and apparati for handling information, energy and material using multimodal cymatic (standing wave patterning, whether stationary or moving) generation, and manipulation, principally of material and energy in vorticoid including concatenated and grouped vorticoid forms, to concentrate, cleanse, separate, transform, produce etc., materials and energy, including without limitation the production of clean water and manufactures materials, the production of net usable energy by effects such as Schauberger and vacuum potential-related, the collection, processing and communication of information by nonlocal quantum coherence (entrainment) of dynamic systems, initially cymatic, viz., vorticoid, the similar transport of lower-dimensionality material patterns, i.e., materials, also to facilitate transport of living organisms, and the tuning of higher-dimensional energy forms, i.e., formative fields, for applications such as healing; a means of fine-tune controlling such systems directly by means of psychoenergetic operator interaction and indirectly by means of conditioned space technologies and vibratory enhancing technologies such as "scalar" treated materials and systems; and by other means described as "gauge-symmetry"-level raising, here, e.g., Bearden; and their combination; and a means of facilitating learning to generate Tiller-effect spacial conditioning (higher gauge symmetry) enhancement using motivated feedback in utilising these systems with spacial conditioning technology assist.

SYSTEM OF METHODS AND APPARATI FOR HANDLING AND MODIFYING INFORMATION ENERGY AND MATTER BY FORMATIVE RESONANCE

BACKGROUND OF THE INVENTION

[0001] This invention relates to an improvement in methods of handling and processing information, energy and matter. It was developed initially to make use of potentials of new technologies, science and industrial art to problems of non-chemical purification, with little or no chemicals added beyond water, of pre-combustion inputs and post-combustion outputs in thermoelectric power generation. The invention extends their application to new, nonobvious and useful systems of methods and apparati for the production, transformation and distribution of matter, energy and information.

PRIOR ART

[0002] With respect to the system of methods and apparati which is the subject of this application, and embodiments therefor, the work of the following, their predecessors and experimentally, clinically or epistemologically near neighbours, form the principal precedent contributions drawn on by this writer: Viktor Schauberger (Austria), Theodor Schwenk (Germany), Hans Jenny (Switzerland), Lawrence Edwards (England), Shafica Karagulla (Canada, United States), Marcel Vogel (United States), Fritz-Albert Popp (Germany), Thomas E. Bearden (United States), Ernst von Bezold (Canada) and William A. Tiller (Canada, United States). The following discussion outlines those contributions applicable to this work as understood by this writer and builds on them to show their relationship to novel, nonobvious and useful aspects of the invention here disclosed.

[0003] Viktor Schauberger was an Austrian forester and technologist whose works are now also widely available in English (1). He observed that when a current in a flowing stream winds centripetally and then centrifugally with an opposite sense of spin, at the turning point of the change of direction of rotation, oxygenation occurs and from this place also there is an energetic flow transverse to the direction of the current, into the stream banks, stimulating the growth of vegetation in those areas. Working with this and similar observations Schauberger was able to invent and frequently to patent 'naturalesque' technologies for diverse applications including trans mountain lumber transport and for transportation; for water purification, energy production, which he identified as environmentally healthier and therefore sustainable in comparison with still-prevalent environmentally destructive mechanistic technologies.

[0004] The centripetal-centrifugal spiral effects he reported (see figure) and made use of ('Schauberger effect') have been applied here in guiding the development of the invention, in light also of observation in the human being's energy field by numerous independent, highly sensitive and skilled observers, of major chakras (see for example S. Karagulla), whirling energetic flexible cones extending well beyond the physical body, situated at and through major glandular centres and aligned in pairs tip-to-tip pointing in opposite directions from the front and back of the body (e.g., B. Brennan and others) set along a central energy channel (called Sushumna in the orient) which runs vertically coincident with the human spine.

[0005] Theodor Schwenk's work on water as a spiraling and projective-geometrically characterisable cosmic sense organ demonstrated, by wheat germination trials using shaken water, the existence and rhythms of cosmic, i.e., extra-terrestrial, atmospherically significant Zeitgeber environmental rhythms, and therefore the importance of taking into account not only the use of vortices but also the significance of macroenvironmental rhythms in cleaning and enlivening water organisms to function harmoniously with the syntropic potential of the biospheric macroenvironment.

[0006] Hans Jenny was a physician living in Dornach, Switzerland who developed the field of Cymatics, creating and filming steady and moving three-dimensional standing waves generally produced with fluid agitated to a standing wave by sound through a loudspeaker base, based on Ernst Chladni's acoustically produced two-dimensional standing wave figures and on an appreciation of the contribution of vibration to the creation of form. Hans Jenny patented a device for making speech visible [ca. 1968; reference].

[0007] In a Chladni figure such as that formed by sprinkled fine sand vibrating on the back of a bowed horizontally held violin, the distribution of nodes and antinodes in the particular mode of vibration of the substrate medium, i.e., the violin back, at the frequencies at which it is being excited, may be displayed by the redistribution of the scattered sand in a pattern corresponding to the position of nodal and or to antinodal points and boundaries, evidently dependent primarily on the size and density of the sand particles. This acoustically mediated resonance has been researched by Jenny, Armin Husemann, Sherry Edwards and others as one of a number of formative principles in the human body. A formative faculty (classically, the facultas formatrix) was cited by Johannes Kepler to explain snow crystal form variation (the body of formative forces of the Earth); was researched in embryology by Erich Blechschmidt; and considered more broadly, has been studied as a phenomenon of internal communication demonstrable optically and functionally e.g., electrically, in all living organisms, by Fritz-Albert Popp and coworkers.

[0008] These examples of energetic formative processes in whole systems, i.e., in bodies of connected parts, demonstrate a formative paradigm which is applied and extended with multimodal energy flows or activity sources, e.g., electro-magneto-gravitic-(/levitatory)-]optic-acoustic and scalar, as well as psychoenergetic, for application in the invention.

[0009] Lawrence Edwards, an English mathematics teacher and biology researcher, showed that tree buds breathe, or fluctuate rhythmically, in winter around an ideal middle form whose projective geometric path curve is related to the golden mean. His vortex spiral calculation methods and examples are cited here as prior art for the production of vortices and their energetic as well as material products which will enliven nature functionally, in the sense Schauberger described and demonstrated, rather than degrading nature.

[0010] Dr. Shafica Karagulla left the Montreal Neurological Institute to do research on higher sense perception, eventually founding with Viola Neal the Higher Sense Perception Foundation in Los Angeles. Karagulla's clinical reporting of the correlation between chakra structure and activity on the one hand, and physiological health status such as patient endocrinology on the other (1965), provide along with the work of V. V. Hunt (UCLA) and other investigators such as R. Steiner a reliable modern base of published observation of some typical human psychoenergetic anatomy and its corresponding function.. This enables those less skilled in the art of such observation to make better use of transitory or fragmentary experimental data and to apply with greater confidence, along with those not making such observations, the findings of others as a source of design modeling information.

[0011] Marcel Vogel, a solid state chemist was instrumental in developing the first magnetic memory disk drive coating for IBM. Vogel published work (1973) demonstrating that psychoenergetic telekinetic phenomena become reproducible with sufficient experimenter self-training of the mind which is the instrument of manifesting such psychoenergetic phenomena. Taken together with the contribution of Tiller, Vogel's work exemplifies a shift to scientific knowledge and ordinary technical application of human capacities which have become a part of the state of the art in healing and are applied in the invention for process control enhancement of which water purification, energy production and telecommunication are three examples.

[0012] Fritz-Albert Popp founded the International Institute of Biophysics (Neuss, Germany, a collaborative research undertaking of dozens of scientists globally. His paradigm shifting discoveries have shown that the activity of a quantitatively small amount of energy, as light, directs and maintains the organisation of the body's biochemical activity, and that essentially all measured bioenergetic functions of organisms, e.g., skin electrical resistivity as measured in humans at hundreds of points on the hands, demonstrate an internal coherence predictive and therefore indicative of health. Normative self-validating measurement of coherence (cf. L. Edwards) in the functioning of cymatic structures is therefore incorporated as a monitoring and feedback control criterion of a preferred embodiment of the invention. Popp patent:

[0013] Thomas E. Bearden, a career research scientist (US Army, retired), wrote the book on Energy from the Vacuum (2002). His paper on Giant Negentropy from the Common Dipole provides a physical science foundation for the Schauberger effect which in its higher order gauge symmetry application appears consistent with W. A. Tiller's description of a second, more psychoenergetically malleable level of the physical world access to which depends on an engineerable coupling function. Bearden's presentation of a corrected and extended physics, taken together with technology which demonstrates it (Patrick et al., U.S. Pat. No. 6,362,718, MEG) provides with Schauberger's work the basis in the present invention justifying a the strategic objective of a water cleaning design for power plants which can be upgraded and modified functionally over time to increase net energy production process efficiencies so as to enable combustibles to be reduced and eventually phased out. Bearden's scientific-historical apparatus also provides a point of comparison with Tiller for quantitative modeling of conditioned space effects incorporated as a functional energy control option within the invention.

[0014] Ernst von Bezold published on the BDnow! Agricultural email list (2001), a description which then was archived by colorado.edu, of a class of technologies, i.e., using shapes combined with rhythmitized materials, based in part on L. Edwards' work on shapes applied to the functional renewal, by applying a thin coating of rhythmitized copper ointment (a therapeutic preparation manufactured by, e.g., Wala or Weleda in Europe, and Merkhur Laboratories in Canada, whose detailed experimental scientific basis is referenced by R. Hauschka), of cow horns used in bio-dynamic agriculture, e.g., in making manure or powdered quartz preparations. The principle of cohering shape and material, intensified by rhythmical treatment of the material (treatment such as may also be found in N. Tesla's purple plates, evidently in the Austrian Johannes Grander's water treatment technology, or in more recent "scalar"-resonant liquid treatment vessels and jewelry) has a parallel in the technology of the great pyramid at Giza and an extension in the biogeometry of A. Kareem as and as presented by R. Gilbert, et al. As described earlier in relation to Edwards' work, this principle is applied here with respect to optimised vortex shaping (cf. Edwards) and material, in this case water, formed and controlled cymatically, with psychoenergetic system control enhancement, and eventually, generation.

[0015] William A. Tiller, former department chair and professor emeritus of material science and engineering at Stanford University, wrote Psychoenergetic Science as a simplification and compilation of three previous related volumes documenting 30 years of paradigm-shifting experimental science on the demonstrable, potential, and instrumentally engineerable enhancement of, the integral functional contribution of consciousness to the matter-energy equilibrium of the object-oriented physical science paradigm presently being transformed by the more interactive understanding of reality shown in quantum physics being applied in such diverse fields such as cryptography, quantum computing and psychoneuroimmunologic therapies. Tiller's empirical work on space conditioning for process modulation, together with his work and that of Vogel on experimenter training for replicability (cf. Charles Tart, "state-specific science") applies and extends the implications of the Indian preceptor Patanjali (ca, 8^{th} century) in a unique and distinctly instrumentally modern, scientifically verified and technologically accessible form. The invention applies both the trained-operator effect and the instrument-mediated spacial conditioning effects to control and enhance multimodal cymatic processing and to and anticipate its transformative progression in part as an operator-initiated and controlled activity with corresponding strategic extension of options of scope and scale of application.

BRIEF SUMMARY OF THE INVENTION

[0027] Essentially, and without limitation of this description to its application in an illustrative preferred embodiment, a cymatic (3- or higher-dimensional Chladni figure-generating) resonant vibrational process is used to induce a rotating standing wave figure in a fluid, such as water, air, plasma, or a slurry including solids, producing a centripetal vortex or vortex of vortices which passing inward through the focus of the tip unwinds from its tip in the same or by induction in an opposite rotation, or meets another incoming vortex tip or tips, at the juncture comprising the tip(s) focus producing differentiable active and potential energetic outputs, and from the focus a likewise differentiable outflow of materials in directions primarily other than that of the axis of tip focus, such as transverse, of least resistance as shaped and sorted within transporting flows of standing waves e.g., whose node-antinode frequencies, amplitudes and spacial configurations are appropriately resonant with selected materials and material-energetic configurations. The forming and modulation of the form may be by external or internal, direct or interferometrically induced, multimodal electro-magneto-gravitic-opto-acoustic and scalar potential drivers controlled by feedback of functional parameters of the manipulated material flow and feedback of the driving energy inputs and their energetic transforms, and having regard to macroenvironmental conditional-probability fluctuations, e.g., in turbulent flow, and, in early embodiments, being fine tuned—later, consequent on operator learning based on feedback with the system as an instrument of learning, increasingly being generated—by operator interaction directly (Vogel), or indirectly using conditioned space effect technology (Tiller) amplification-modulation or other higher gauge broken symmetry operations (Bearden), to bias threshold condition probabilities favourably in respect of intended states of the system.

BRIEF DESCRIPTION OF THE DRAWINGS

[0028] Annotated List of FIGS. **1**. to **4**(*a*)-(*f*)

[0029] FIG. **1**. Background of the invention and cross-reference for FIG. **3**. which illustrates a feature of a preferable embodiment of the invention:

[0030] An example from river current flow, "The Inner Picture of the Dynamics of Current Flow", showing inward spiraling with reversal of spiral direction at the point, i.e., in the region, of start of outward spiraling—and indicating transverse-vectored radiant propagation of energy, as well as in this context reactive enhancement, i.e., oxygenation—is from Schauberger, 1941, as reproduced in Coates, Vol. 1, 1997.

[0031] FIGS. **2** and **3**. Illustrations of features of preferable embodiments of the invention:

[0032] FIG. **2**. A sketch of a sample cross-section functionally spiraling pathway, i.e. here as spirally-fluted piping, whether formed structurally, or through the formed and formative injection of materials such as water into and as a part of the pathway, or in part or in whole energetic-dynamically, or by some combination or permutation of these.

[0033] FIG. **3**. A sketch of a sample complex vortex of vortices, modeled on the inventor's observation as well as on descriptions, of naturally-occurring and developed or "built" complex vortex structures which may be characterised as dynamically stable n-dimensional "standing wave" structures. The example is of a collinear pair of complex vortices shown in oblique cross-section; to the left in the figure is appended a dotted-line indicator of a contiguous, expansion-contraction vortex figure such as may be found in FIG. **1** with a second point of maximal vortex centripetal concentration, as may also be seen in FIG. **4**(*f*). This vortex meeting, or transition, point is a focal region of energy concentration and release which as a focal point of modulation (depending also on vortex spin directions) can be used to amplify the modulating signal's effect in the centrifugal or expansive phase or, respectively depending on vortex spin directions, to modulate energy released along another vector from the focal region; for a naturalesque example; see FIG. **1**.

[0034] FIG. **4** note: Such sets of vortices can be concatenated in various geometries—linearly, in rings, nested, etc.—as information energy and materials handling and transformation structures, e.g., in the processing of water of whatever phase, and gases or other materials, of energy, and of information, associated with combustion, of coal, etc; with other manufacture of energy and of material substance in preferred composition, form, state, and the production of purposed information-rich structures or forms and structures or forms for processing information; with the sensing or other collection, processing, communication of information and associated energetic and material entities, e.g., as information carriers, viz., modulating and as modulators, locally and nonlocally, for example using functionally entrained (i.e., resonantly tuned) nonlocally paired single or doubled (for energetic balance) sets of more or less triple vortices, e.g., three-dimensionally depending on intended function, which are monitored and modulated at the origin (see **4**(*e*) below), e.g., using one or more members of the class of modulators listed above, especially operator- or user-specifiable modulators, to enable transfer of informational, energetic, material pattern momentum between the nonlocally paired vortex sets, in order to facilitate convenient transfer of process-related patterning for the effective replication of data, of energy states, or transfer under competent operation conditions of low-dimensional-number patterns that act as localizing carriers for higher-dimensionally-resonant homeostatic structural fields and their associated states, i.e., principally in living organisms. The same principle can be applied reflexively to enhance holotropic pattern stability of organisms with respect to an operator-programmable template field; e.g., as two examples among many, for conservation and improvement of biotic function and its patterned energetic basis using an algorithmically-controlled amplifier to enhance food stability and therefore conservation or to support healing based on modulation of a resonantly shaped and directed energy flow using a reflexively applied template which is functionally operator-enhanced.

[0035] As cited above, a mathematical apparatus for calculating projective-geometrically visualisable vortex and related path curves, including but not limited to a sample computer program, and sample illustrations of the families of curves employed here, which it is proposed are a functional correspondent class of the shapes observed and then designed and used by V. Schauberger, may be found in Lawrence Edwards' work, inter alia: The Vortex of Life, 1993. See also articles in Mathematical-Physical Correspondence; and, The Field of Form, 1982. FIG. **4** illustrates examples of some applicable projective-geometric curves and their calculation from Edwards (1993); of classes of curves to be applied and based on the mathematical descriptions of their classes, to be used in examples, indicated descriptively in the foregoing (i.e., in the accompanying) text, of preferred embodiments of the invention.

DETAILED DESCRIPTION OF THE INVENTION

[0036] The present invention now will be described more fully with reference to the general inventive concept, and to illustrate embodiments of the invention. As this invention may be embodied in many different forms, its scope should not be construed as limited to the exemplary embodiments set forth; rather, the examples are provided to indicate a scope of potential preferred embodiments to those skilled in the art.

[0037] The present invention of a system of methods to handle information, energy and materials and to modify their properties relates to the modification by manipulation iteratively (including but not limited to, in particular, recursively; the term "iteratively" is so used throughout), simultaneously and prospectively or retrospectively, of the potential and manifest energetic, temporal and spacial coordinate, motional and orientational, coherence and informational or entropic status, dimensionality including but not limited to metric (dimensional curvature), combination or dissociation, of materials in amounts and states ranging from particle to compound and bulk mass, including but not limited to plasma, gas, solid and liquid states singly, intermixed or combined, making use of one or a coordinated combination (including but not limited to, as the case may be, ordered combination, i.e., permutation; "combination" is so used as an inclusive term, throughout) of more than one structure and system of vibration and resonance of material or energetic shape, including but not limited to environmental Zeitgebers or related factors or their artificial analogues, in a feedback or resonance-controlled manner permitting dynamically active, i.e., reflexively, iteratively and synchronically varying differentiation, integration, transformation including but not limited to metamorphosis or conversion from one state to another, of informational, energetic and associated material states, systems, forms and entities.

[0038] The invention consists of a unimodal or multimodal integrated system of methods as outlined here to handle information, energy and material and modify their properties, including but not limited to local and nonlocal interaction, patterning and coherence.

[0039] An example of a class of embodiments is as it relates to communication of information, energy and material, particularly between the holographic sub-quantum and quantum-level entrainment and cross-modulation of asymptotically and hyperbolically n-dimensionally pattern-matched, e.g., including but not limited to in particular functionally synchronous nonlocal, systems of information, energy and material.

[0040] Another example of a class of embodiments is as it relates to holotropically "self"-similar precursorial re-equilibration of organisms and entities, including but not limited to in particular their energetic (viz. their persisting or durable sub- and quantum-resonant) template or formative pattern in a range of applications from medicine to physical device and structures maintenance, to re-establish a proximal functional and structural wholeness at a higher level of holistic functional coherence, in particular also therefore to re-tune them optimally with and to a resonant pattern of macro-environmentally current syntropy with its accessible dimensional and nondimensional substates. "Vis medicatrix naturae per facultatem formatrix": i.e., re-tune organism to their archetypal (basic, healthy) formative patterns in harmony with the macrobiosphere, "The healing life of nature [accessed] through the formative faculty".

[0041] An example of a class of embodiments preferable for their obviously immediately beneficial and pertinent application relates principally to the energies and material substance associated with solids, with liquid and gaseous fluids and solids associated with them; to plasma, and associated quantum-energetic (viz., respectively, subquantum-energetic, i.e., including but not limited to, in particular, ["quantum"-]nonlocally entrained energetic-potential such as so-called zero-point) states.

[0042] A specific application in this class of embodiment is its use for the pre-, real-time ongoing, and post-treatment of fluids, in particular, water and gases including but not limited to related particulates, associated with combustion, in the processing, particularly the cleaning, of pre-, combusting and post-combustion gases, in particular, respectively, gaseous/ified combustants, products and proximal energy, materials and energetic patterns associated with combustion of e.g., hydrocarbons such as coal; by the use singly and in combinations; continuously, and discontinuously, through design-resonant, or forced pulsation inducing turbulence, pulsation, cavitation; of physical-structurally, or energetically, e.g., acoustically; magnetically; etc.; functionally spiraling, e.g., spirally-fluted piping, pathways which may be used to induce or facilitate; optionally with 2, 3 or more dimensional Chladni-figure, i.e., cymatic, dynamically shifting resonance/feedback-controlled electro-magneto-gravitic-levitatory-opto-acoustic-temporal-spacial standing-wave patterns, including but not limited to scalar Whittaker fine structure signaling particularly for thermal behaviour control of materials, and application of Grander and Tiller field-effect systems; and also, optionally with a class of directly operator-driven phenomena, e.g., Keely-effect, Vogel-method or "Hutchison-effect" induction;

[0043] to condense or rarefy and drive spacially, i.e., to segregate, mix, react, shape, etc., said fluids, viz. gases and their constituent and included substances including but not limited to precipitates, elements and compounds to be formed or dissociated, fractionated out, otherwise modified, and to assist in the production of energy; especially, in particular, where certain forms are approached or striven for or referenced, such as the mean as well as ideal value cycloid space curve families described by Lawrence Edwards in the life of nature, materials in these forms being evidently energizing resonant transducers of water quality renewal and related effects; and forms such as the bio-geometrically-analysed designs—e.g., concavities in structures, such as, e.g. a gradual half-degree indentation of each of the outer upper surfaces of the Great Pyramid at Giza used to induce "horizontal negative green", and other, cone-pendulum-response states as presented and described by A. Kareem, R. Gilbert and others—which may be favourable or conducive to the improvement of informational content, energy and material, e.g., i.e., in this case of quality of water and gases and their forms and behaviours, especially combustion-associated gases and water in whatever phase, and of their environment, and of related cleansing, reactive or structural-energetic-chemical including but not limited to biochemical stabilizing activity in this setting as well as in other settings such as biochemical cleansing, stabilisation, renewal of living organisms, their environment and precedents including but not limited to inputs and succedents including but not limited to outputs.

[0044] Modulation preferentially may be varied in feedback, resonantly simultaneous with, or preceding (e.g., within entrainment parameter values range) synchrony with, environmental Zeitgebers and their measures, e.g., using rhythmitized shapes (rhythmitised shaping functions in classes such as that of the Great pyramid, cow horns and other natural structures as resonators, described as mathematical function classes by L. Edwards), with respect to the patterns shown by astronomical ephemerides, and the mathematical descriptions of, in particular, planes and other shapes or figures formed among massive bodies during their transits, by astronomically related variations in the values of the tensor Tau sub jk and associated described functions including but not limited to those identified by G. Unger of Dornach, Switzerland, and by associated indicators; to optimise negentropic as well as entropic functions severally and in combination.

[0045] A specific class of instances of this kind of embodiment would utilise rotating multimodal fields and resonant "radiative" and "field" effects, whether by gross energetic induction as described or by resonant rhythmitised shaping or by indirect Tiller-type or directly operator-programmed tuning or combinations to induce essentially, preferably by means without moving parts,

[0046] the enlivening of energy and of material, i.e., of water;

[0047] pre-cleaning and conditioning of gases; including but not limited to, for both water and combustion-related gases, electrical or other energetic charging or programming, e.g., magnetic induction of appropriate coherent spin and precession of particles and other structures, e.g., hydrogen proton precession;

[0048] cymatic vortical motion including but not limited to, based on the work of Viktor Schauberger, Theodor Schwenk and others, centripetal as well as, as may be useful or conducive in application, centrifugal, and alternating centripetal/centrifugal, with "braiding" of flows to facilitate blending—respectively separation of succedent materials and states—of spiraling gases and water; leading to improved mixing, modification and separation of materials, and improved control of energy production, improved cleansing and production of associated materials in usable higher quality lower cost form than might otherwise be the case;

[0049] modification of gasification, precipitation, and endo/exothermic processes by Whittaker fine structure signaling, by Grander spacial and magnetic induction, et. seq., especially for real-time process- and flow-control stabilisation;

[0050] modification of the foregoing and of other processes, states and conditions through operator-controlled intent and concentration of energies, indirectly by programmable-unit Tiller "field effect" action, viz. gauge-symmetry level modulation, as well as directly, including but not limited to Keely-technology and Vogel-methodology effects.

[0051] An example of a design which preferably embodies elements of the foregoing in an application to facilitate production of clean combustion by-products of coal and of other combustibles or pre-combustible feedstocks and their combustion processing materials and systems, the materials being principally water and air, with an optimal net production of environmentally life-enhancing (i.e., also therefore, minimally life-degrading) quality and quantity of energy, material and information especially bioinformation, is as follows:

[0052] Iteratively, and by resonance including but not limited to pre-emptive or pattern-anticipatory entrainment-leveraging e.g., phase-lock, signaling,

[0053] 1. Form water and gas flows architecturally, i.e., physical-structurally using the patented and unpatented built as well as the designed examples from among: R. Steiner; especially, V. Schauberger with numerous illustrations of examples in patents and other literature to be cited; T. Schwenk; J. Grander; and for informational, energetic and materials modulating effects using shaped rhythmitised materials, E. von Bezold (2001); and, by means of a "complex" vortex, i.e., a set of complex vortices each comprised of multiple vortices arranged in groups as dynamically stable standing-wave "cells", the focal point of each of which may centre on and be contiguous with the focal point of a corresponding collinear vortex whose mouth is pointed in the opposite direction to the first, or with the focal points of a number of vortices dynamically balanced energetically and in space, all with one another.

[0054] 2. Also shape the streams, e.g., for a first approximation as exemplified in the foregoing paragraph, vibrationally by tuned coherent energetic induction and modulation magnetically/diamagnetically, opto-acoustically-thermally using dynamic Chladni-figure standing-wave vortices, i.e., after the cymatics of H. Jenny et. al.—also approached by the flow forms of Wilkes, articulated by A. Husemann and others, also alluded to mathematically by G. Adams, by P. Forchheimer, later by T. Schwenk (1954) who cites I Prigogine in the context of sensitive control-response; discussed mathematically by R. Abram and concurrently and subsequently especially in the work of L. Edwards—in the classes of shapes expressed mathematically by L. Edwards (1993) who provides calculation methods, computer software and diagrammatic illustrations: oscillating, varying, within and around syntropic, life optima "antenna" shapes, e.g., mean as well as ideal shapes, tuned over time to work with principal macro-environmental (Zeitgeber) rhythms; and transformed (e.g., by rotation and by translation in flow, e.g., induced acoustically or by optically-tunnelled electromagnetic radiation, e.g., amplitude-, frequency- and waveform-specific light, such as squeezed light or other coherent as well as incoherent light) metrically and physico-chemically, pulsated, and otherwise modulated to induce enhanced laminar flow, controlled turbulence, and cavitation-reformative collapse cycles, including but not limited to cycles that are rhythmically- i.e. resonantly-enhanced; and further to modulate the sensitive, cf. T. Schwenk, non-equilibrium, cf. I. Prigogine, self-organising activity.

[0055] 3. Concurrently, modify the processes locally and globally, in part and in whole, using as appropriate the means described in 1. and 2., and other available signalling energizing systems as modulators for the above control systems and as net additional inputs and, as appropriate, use energetic outputs to be fed back into the system as controlling modulators; including but not limited to, as examples, electrostatic dispersion; complementary electrical charging; electrolysis; magnetic, endo/exothermal, other emf or energetic treatment including but not limited to macroenvironmental signals, unamplified and amplified; to, e.g., increase, maintain or reduce solubility; flow formation, as described above, to enliven fluids; centripetal cyclones, compression vortex mixing and transformation of inputs, e.g., vortical compression wave precipitation threshold modification; space state, time state and information coherence system behaviour state programming, e.g., via proximity field conditioning, e.g., Tesla purple plate technology or other "scalar treated" programmed resonators, characterisable for example in quartz by a Cartesian matrix spaced throughout the material of silicon atoms each containing a proton with a doubled Lissajous figure; Tiller-effect units; Grander units; Whittaker structure modulation to improve e.g., output cleansing, output precipitation conditions as well as to optimise thermal production efficiency exothermically internally and endothermically at specified system functional boundaries to eliminate net environmental negative impact and, as with the whole system, optimise positive impact; further to the description in 2., use of sound and acoustically-tuned EMF, e.g., as heterodyned fields, and other means to induce mass hyperacceleration and velocity effects, and other methods of catalysis, e.g., to improve reaction chemistry, hydroxyl radical and hydrogen chemistry optimization, etc.; further applications integrated synergically with above processes, of acoustic, especially pulsating, and EMR (electromagnetic radiation) and other radiative effects other than magnetic; e.g., for improved control of combination-dissociation processes by sound, acoustico-magnetic, infrared, UV, etc., within transient standing-wave cells whose opto- and magneto-acoustics are, for example, like those demonstrated optically by a cyclone, a tornado or an optical fibre, i.e., distinctly self-contained or transmissive in a parametrically-specific manner.

[0056] Specific terms employed for illustration should be read in a generic and descriptive sense only and not for purposes of limitation. The scope of the invention is further set forth in the following claims.

1. A system of methods and apparati for handling information, energy and material using multimodal cymatic (standing wave patterning, whether stationary or moving) generation, and manipulation, principally of material and energy in vorticoid including concatenated and grouped vorticoid forms, to concentrate, cleanse, separate, transform, produce etc., materials and energy, including without limitation the production of clean water and manufactures materials, the production of net usable energy by effects such as Schauberger and vacuum potential-related, the collection, processing and communication of information by nonlocal quantum coherence (entrainment) of dynamic systems, initially cymatic, viz., vorticoid, the similar transport of lower-dimensionality material patterns, i.e., materials, also to facilitate transport of living organisms, and the tuning of higher-dimensional energy forms, i.e., formative fields, for applications such as healing.

2. A means of fine-tune controlling such systems directly by means of psychoenergetic operator interaction and indirectly by means of conditioned space technologies and vibratory enhancing technologies such as "scalar" treated materials and systems; and by other means described as "gauge-symmetry"-level raising, here, e.g., Bearden; and their combination.

3. Means of facilitating learning to generate Tiller-effect spacial conditioning (higher gauge symmetry) enhancement using motivated feedback in utilising these systems with spacial conditioning technology assist.

4. Further, based on the foregoing, all related dependent claims which may properly be construed from the foregoing.

(57) **ABSTRACT**

Provided is an apparatus for harvesting energy from a microwave. An apparatus for harvesting energy from a microwave in an electricity storage system of a building, includes: a plurality of rectennas arranged with a predetermined length according to characteristic of microwave to be absorbed, and configured to collect microwave in the atmosphere and convert the collected microwave into electric energy; a current converter configured to convert the electric energy outputted from the rectennas into a storable current; and a charging tank configured to store the current outputted from the current converter, wherein the arranged rectennas are attached to an outer wall of the building, and the rectennas attached to the top of the building are printed in a transparent conductor on the surface of a solar cell.

APPARATUS FOR HARVESTING ENERGY FROM MICROWAVE

CROSS-REFERENCE(S) TO RELATED APPLICATIONS

[0001] The present invention claims priority of Korean Patent Application No(s). 10-2009-0037190, filed on Apr. 28, 2009, which is incorporated herein by reference in its entirety.

BACKGROUND OF THE INVENTION

[0002] 1. Field of the Invention

[0003] The present invention relates to an energy harvesting apparatus; and, more particularly, to an apparatus for harvesting energy from a microwave.

[0004] 2. Description of Related Art

[0005] Generally, a microwave is energy generated from a flow of electricity and magnetism and is also called a radio wave. That is, an electric field and a magnetic field are simultaneously generated around an area where vibration occurs while electricity is flowing, and a wave generated while the electric field and the magnetic field vary periodically is called a microwave. Such a microwave exists everywhere.

[0006] A microwave may be classified into electric fields generated by a voltage, and magnetic fields generated by a current. The microwave is generated from any product using electricity, for example, power transmission/distribution lines, electric appliances, and so on.

[0007] An electric field is generated in a perpendicular direction from a source in a straight-line shape and is easily removed or weakened by trees, buildings, human being's skins, and so on. A magnetic field is formed in a circular shape around a source and is not easily removed or weakened by certain objects or materials.

[0008] A microwave is classified into a gamma ray, an X ray, an ultraviolet ray, a visible ray (light), an infrared ray, and a radio wave (ultrahigh frequency radio wave, high frequency radio wave, low frequency radio wave, and very low frequency radio wave) in descending order of frequency. Accordingly, the radio wave refers to a microwave with a frequency of 3,000 GHz or less, and it is indispensable to daily life because it is used in various types. However, the very low frequency radio wave and the low frequency radio wave generate an electric field and a magnetic field. Hence, if a human body is exposed to the very low frequency radio wave or the low frequency radio wave for a long time, a body temperature is changed and a biorhythm is unbalanced, which is very likely to cause diseases. For example, search results were reported that the very low frequency radio wave and the low frequency radio wave might cause the reduction in the number of sperms for men, and might cause menstrual irregularity and birth defects for women. Furthermore, since a brain tumor might be caused in serious cases, the World Health Organization (WHO) conducted investigations, and harmfulness of the microwave has been revealed.

[0009] Examples of microwaves around our surroundings may include effective isotropically radiated power (hereinafter, referred to as "EIRP") radiated from a near base station, a magnetic field generated around a high pressure power station or a transformer substation, and strong electromagnetic interference (hereinafter, referred to as "EMI") generated in communication/electricity systems with high power consumption. Therefore, there is a need for methods for ensuring safety from the microwave environmental problems. Moreover, methods for reproducing harmful microwave into electric energy have attracted attention.

[0010] Meanwhile, due to concerns about exhaustion of finite resources such as petroleum energy, there is a need for methods for ensuring stable and regular energy. The microwave always exists around us. Therefore, wireless power transmission and energy reproduction technologies using microwave and radio wave have attracted attention as new research fields due to the exhaustion of fossil energy.

[0011] A representative new energy reproduction technology is to use a solar heat. The technology using a solar heat is applied in many places. However, an energy reproduction technology using a solar heat has a large number of variable parameters. Sufficient energy can be obtained during the daytime, but energy is consumed at night. Also, the energy efficiency is changed according to climatic condition. Specifically, efficiency of energy is high when a solar heat is strong, but it is low when it rains or snows. An amount of energy produced is also always varied. Moreover, since the sun always moves from the east to the west, optimal energy collection is difficult.

[0012] Like the solar heat, a wind power also has a large number of variable parameters. A blowing wind rotates blades of a wind power generator and an electric generator is operated by the rotation of the blades, resulting in production of energy. However, when no wind blows, energy cannot be produced. Also, the wind power generator must be installed in a windy area. Like this, location requirements for the wind power generator are hard to meet.

[0013] Therefore, there is a need for stable energy supply, instead of variable energy production of a solar heat or wind power.

SUMMARY OF THE INVENTION

[0014] An embodiment of the present invention is directed to providing an apparatus for ensuring a stable energy source.

[0015] Another embodiment of the present invention is directed to providing an energy harvesting apparatus capable of solving energy harvesting limitation caused by existence of variable parameters and so on.

[0016] Another embodiment of the present invention is directed to providing an energy harvesting apparatus capable of reducing influence of microwave on a human body.

[0017] In accordance with an aspect of the present invention, there is provided an apparatus for harvesting energy from a microwave in an electricity storage system of a building, which includes: a plurality of rectennas arranged with a predetermined length according to characteristic of microwave to be absorbed, and configured to collect microwave in the atmosphere and convert the collected microwave into electric energy; a current converter configured to convert the electric energy outputted from the rectennas into a storable current; and a charging tank configured to store the current outputted from the current converter, wherein the arranged rectennas are attached to an outer wall of the building, and the rectennas attached to the top of the building are printed in a transparent conductor on the surface of a solar cell.

[0018] In accordance with another aspect of the present invention, there is provided a system for harvesting energy from a microwave in an electricity storage system, which includes: a plurality of rectennas having a predetermined length and configured to collect a magnetic field among microwaves radiated from a high voltage cable and convert the collected magnetic field into electric energy; a current converter configured to convert the electric energy outputted from the rectennas into a storable current; and a charging tank configured to store the converted current, wherein the rectennas are spaced apart from the high voltage cable by a predetermined distance and arranged in a form of a fence so that a magnetic field does not affect a human body.

[0019] In accordance with another aspect of the present invention, there is provided an apparatus for harvesting energy from a microwave radiated from a system with an antenna, which includes: a plurality of rectennas configured to absorb a microwave radiated in an unwanted direction among microwaves radiated from the antenna and convert the absorbed microwave into electric energy; a current converter configured to convert the electric energy outputted from the rectennas into a storable current, and a charging tank configured to store the current outputted from the current converter, wherein the rectennas are spaced apart from the antenna by a predetermined distance in the unwanted direction and arranged in a certain form to shield the microwave.

[0020] Other objects and advantages of the present invention can be understood by the following description, and become apparent with reference to the embodiments of the present invention. Also, it is obvious to those skilled in the art to which the present invention pertains that the objects and advantages of the present invention can be realized by the means as claimed and combinations thereof.

BRIEF DESCRIPTION OF THE DRAWINGS

[0021] FIG. **1** is a conceptual diagram explaining a method for harvesting energy from a microwave by using an existing solar cell system in accordance with an embodiment of the present invention.

[0022] FIG. **2** is a conceptual diagram explaining an energy harvesting method using a microwave radiated from a base station in accordance with an embodiment of the present invention.

[0023] FIG. **3** is a conceptual diagram explaining an energy harvesting method using a microwave generated around a high pressure power station and a transformer substation in accordance with an embodiment of the present invention.

[0024] FIG. **4** illustrates an array structure of a rectenna for harvesting energy in accordance with an embodiment of the present invention.

[0025] FIG. **5** is a conceptual diagram explaining an energy harvesting apparatus using an EMI microwave generated from high-power wireless facilities and communication equipment in accordance with an embodiment of the present invention.

[0026] FIG. **6** is a conceptual diagram explaining an energy harvesting apparatus using microwave energy radiated from side lobes among microwaves radiated from a general antenna in accordance with an embodiment of the present invention.

DESCRIPTION OF SPECIFIC EMBODIMENTS

[0027] The advantages, features and aspects of the invention will become apparent from the following description of the embodiments with reference to the accompanying drawings, which is set forth hereinafter. Exemplary embodiments set forth herein may be modified in many different forms, and these embodiments are provided so that this disclosure will fully convey the concept of the invention to those skilled in the art. In the drawings, antennas, devices, or buildings are exaggerated or illustrated in different forms for clarity.

[0028] Prior to description of embodiments with reference to the accompanying drawings, an overview of the invention will be presented.

[0029] Wireless microwaves always exist around us. Examples of the wireless microwaves include microwave generated from a power station, EMI generated from a wireless device, and RF wave, microwave and millimeter wave always existing in the atmosphere.

[0030] The present invention relates to an apparatus for harvesting energy from these microwaves. Unlike a solar heat, microwaves always exist. Meanwhile, damage is often caused by EMI, or microwave environment is frequently misunderstood. Therefore, the present invention is directed to providing methods for ensuring stable and regular energy around us, under serious concerns about microwave environment problems and exhaustion of petroleum energy.

[0031] Methods for harvesting energy in accordance with embodiments of the present invention will be described below.

[0032] A first embodiment of the present invention relates to a method that uses an existing power collector where a rectenna is further installed in a solar cell which has been widely applied. The rectenna is a power collecting antenna made of a transparent conductor.

[0033] A second embodiment of the present invention relates to a method that generates new electricity by using EIRP radiated from a near base station and ensures safety from microwave outputted from the base station.

[0034] A third embodiment of the present invention relates to a method that ensures safety around a high pressure power station and a transformer substation, while reproducing electric energy from a magnetic field, which is a main cause of microwave generated at a high pressure power station.

[0035] A fourth embodiment of the present invention relates to a microwave energy reproducing method employing a method for shielding strong EMI generated in a communication and electric system with high power consumption.

[0036] A fifth embodiment of the present invention relates to an electric energy reproducing method that uses energy corresponding to side lobes among radiation patterns in order to control and shield microwave radiated from a communication repeater, a broadcast repeater and a base station to other areas.

First Embodiment

[0037] FIG. **1** is a conceptual diagram explaining a method for harvesting energy from a microwave by using an existing solar cell system in accordance with a first embodiment of the present invention.

[0038] Generally, most private homes or offices such as buildings receive AC power from an external transformer **108**, and most electronic appliances use electric energy by employing an AC-DC converter. However, since a large amount of energy is lost during the conversion process, many studies have been conducted to reduce the number of AC-DC conversions by providing a DC power supply system.

[0039] Therefore, in the new energy reproduction technology, energy is stored and used by employing a DC storage battery for a DC power supply.

[0040] A representative new energy reproduction technology is to use the sun **101**. Electricity is generated by using light and heat radiated from the sun **101**. As the method using the sun **101**, there is a solar heat technology and a photovoltaic power generation technology. In the following description, the sun **101** means both the solar light and the solar heat. In the case where the sun **101** means the solar light and the case where the sun **101** means the solar heat, the same reference numeral is used.

[0041] The solar heat technology uses a heat collector to convert solar radiant energy into heat energy, and the photovoltaic power generation technology uses a solar cell to convert a solar radiant energy into an electric energy. The solar heat technology is a photothermal field using a wave property of the sun's rays and is applied to air conditioning of buildings and water heating through absorption, storage and heat conversion of the solar heat **101**. The photovoltaic power generation technology directly converts the solar light **101** into electric energy and generates power by using a solar cell which generates electricity due to the photoelectric effect when receiving the sunlight.

[0042] A photovoltaic power generation system includes a solar cell module **107**, a rectifier **104** used as a power converter, and a charging tank **105** configured to store a rectified DC current.

[0043] The solar cell module **107** is installed in the roof or exterior of the building, where an amount of sunshine is sufficient, in order to receive a large amount of the solar light **101**. Energy generated from the solar cell module **107** by the use of the solar light **101** rectifies an AC current into a DC current having one direction through the rectifier **104**. The DC current outputted from the rectifier **104** is stored in the charging tank **105** and used in a computer **106** or other household electric appliances.

[0044] In addition to the solar heat **101**, a wind power generator **103** is used as another new and renewable energy technology. The wind power generator **103** generates induced electricity by converting the kinetic energy of the wind into torque and supplies the induced electricity to power systems or consumers.

[0045] The wind power generator **103** includes a momentum conversion system configured to absorbing and converting energy of the wind power, a power transmission system, a power conversion system, and a control system. The respective components that store the electric energy by using the wind power are mutually coupled to function as a whole system. The induced electricity generated during the execution of the function is converted into a DC current trough the rectifier **104** and stored in the charging tank **105**.

[0046] The current stored in the charging tank **105** by the solar heat **101** or the wind power generator **103** may be used in household electric appliances. However, the solar heat **101** or the wind power generator **103** has a changeability, that is, the quantity of energy generated is changed according to circumstances.

[0047] Microwave has a very low energy, compared with the wind power or the solar heat **101**, but it radiates the same energy at all times. Also, since microwave has less variable factors, the system can be easily configured. Furthermore, compared with the solar cell using semiconductor, the antenna configuration is inexpensive and simple.

[0048] The rectenna, which is an antenna configured to collect power from microwave, is a compound word of "antenna" and "rectifier." The antenna is configured to receive microwave, and the rectifier is configured to convert the received microwave into electric energy. In order to receive maximum power, the rectenna has a matching circuit and input/output impedance different from those of a general antenna. Like the general antenna, the rectenna may be fabricated in various configurations. Among them, a patch configuration is advantageous to a packaging and easy to fabricate in an array form because of its two-dimensional structure.

[0049] In addition, the rectenna may be made of a transparent conductor or a general conductor. Power generated through the rectenna may be used in the rectifier **104** and the charging tank **105**, which is the existing renewable energy system, without modifications. Hence, additional installation and fabrication costs can be remarkably reduced.

[0050] Furthermore, the rectenna may be fabricated using an inexpensive painting scheme. The rectenna configured by applying the painting scheme to a transparent conductor may be fabricated in a planar type and used by attaching on the solar cell module **107**. If the rectenna is implemented with the transparent conductor, energy can be ensured twofold by overlapping the rectenna on the solar cell. In addition, the rectenna may be attached to the outer wall of the building, the top of the building, or the window where energy can be easily collected. The rectenna may convert the absorbed microwave into electric energy. If a desired microwave is absorbed through the rectenna, the rectenna resonates at a specific frequency. Accordingly, if using a frequency function, the length of the rectenna may be determined according to the frequency of the microwave.

[0051] Moreover, as illustrated in FIG. **4**, the rectenna may be arranged in an array form in order to improve energy received through the power collecting antenna.

[0052] FIG. **4** illustrates an array structure of a rectenna for harvesting energy in accordance with an embodiment of the present invention.

[0053] In the case of one energy collecting antenna **402**, an amount of energy collected is small. Hence, a plurality of antennas **402** are arranged in an array form. Compared with the case of using one antenna **402**, an energy collecting antenna unit **401** configured in an array form can increase an amount of energy received. When designing the energy collecting antenna unit **401** in the array form, the antennas **402** must be arranged considering antenna area and inter-antenna interference.

[0054] The energy collecting antenna **401** may be fabricated not in an antenna structure but in a resonance structure or an electromagnetic induction structure. In particular, in the case of using the rectenna to collect low frequency microwave, the resonance structure and the electromagnetic induction structure may be advantageous.

[0055] As described above, the use of the power collecting antenna can solve the problems of microwave generated inside the house or existing around the house. That is, various kinds of microwaves generated in a living space can be removed, and the electric energy can be reproduced by using the microwave.

Second Embodiment

[0056] FIG. **2** is a conceptual diagram explaining a method for harvesting energy from a microwave radiated from a base station in accordance with a second embodiment of the present invention.

[0057] For convenience of life, a large number of mobile communication base stations **201** are installed around us. However, the intensity of microwave will be very strong if the mobile communication base stations **201** are installed at locations very near from the house or village **204**. The above-described example is not limited to the mobile communication base station, and may include a broadcast repeater and so on. In this case, a shield **205** may be installed in order for stable communication and protection of the house or village **204** from the strong microwave **203**.

[0058] Like the embodiment of FIG. **4**, the shield **205** may be configured in an array form, or may be made of a transparent conductor and installed over the village, considering an amount of sunshine. The shield **205** is not limited to the embodiment of FIG. **5**, and may be modified in various forms. For example, the shield **205** may be installed in a fence form.

[0059] Furthermore, the installation of the shield **205** makes it possible to receive the strong microwave **203** radiated from the mobile communication base station **201** and then reproduce energy.

[0060] Generally, the energy radiated from the mobile communication base station **201** is EIRP of more than 10,000 W. The radiant energy decreases with the inverse square of distance (d). As one example, in the case of using the existing rectenna technology and charging technology, the energy of 480 mW is produced at the distance of 1 m in the antenna area of 6×6 cm^2, the energy of 4.8 mW is produced at the distance of 10 m, and the energy of 48 μW is produced at the distance of 100 m. Also, the energy of 13.3 mW is produced at a distance of 100 m in the antenna area of 1 m^2, and the energy of 1.3 W is generated in the antenna area of 10 m^2.

Third Embodiment

[0061] FIG. **3** is a conceptual diagram explaining a method for harvesting energy from a microwave generated around a high pressure power station and a transformer substation in accordance with a firth embodiment of the present invention.

[0062] The high pressure power station or transformer substation **301** or the high-voltage power transmission line **302** is considered as obnoxious facilities, and persons are reluctant to live around there. This is because persons are concerned about damage from microwave exposure because low frequency microwave is generated from those places. A low frequency generates a strong magnetic field. The control of such a magnetic field may be impossible even by the installation of a high fence.

[0063] Therefore, the method of FIG. **3** is to keep a magnetic field, which is a main cause among microwaves generated at the high pressure power station, reproduce electric energy, ensure the safety around the transformer substation, and harvest energy by using the magnetic field.

[0064] As an antenna for detection of a magnetic field, a low-impedance loop antenna is generally used. Like the embodiment of the present invention, when a frequency is very low just like microwave radiated from the high pressure power station and the transformer substation, magnetic field components can be collected by using a resonant loop antenna or an inductive coil.

[0065] In this embodiment, the resonant loop antenna, the magnetic resonator, and the electromagnetic induction coil for removing the magnetic field **307** may be fabricated in a form indicated by reference numeral **304**, and they are arranged around the fence **303** so that microwave is prevented from leaking out of the high pressure power station **301** and the high-voltage power transmission line **302**. Also, the magnetic field **307** and the microwave collected at the fence **303** configured with the above-described components are prevented from leaking out and converted into electric energy. That is, by providing a reproduction unit (not shown) for storing energy by converting energy of the magnetic field and so on collected at the fence **303** into an electric form, energy stored in the electric condenser (not shown) may be used.

[0066] Furthermore, by installing the shield **306** as well as the fence **303** at the village **305** near the high pressure power station **301** or the high-voltage power transmission line **302**, like the embodiment of FIG. **2**, energy can be reproduced by collecting microwave that is not prevented by the fence **303**. Moreover, the installation of the shield **306** can protect the house or village **305** from microwave.

Fourth Embodiment

[0067] FIG. **5** is a conceptual diagram explaining an energy harvesting apparatus using EMI microwave generated from high-power wireless facilities and communication equipment in accordance with a fourth embodiment of the present invention.

[0068] The high-power wireless facilities or communication/electric system **501** consumes high power, which may cause strong EMI. Therefore, a method for protecting from EMI and reproducing energy by collecting EMI noises will be described below.

[0069] An energy collecting antenna **503** is installed in the outside of the high-power wireless facilities or communication/electric system **501** in order to remove EMI noises generated when driving the high-power wireless facilities or communication/electric system **501**. As described above, the energy collecting antenna **503** may be implemented in an array antenna type, and a printing scheme may be applied on a transparent substrate. In the case of applying the printing scheme on the transparent substrate as described above, operation states of the high-power wireless facilities or communication/electric system **501** can be easily confirmed. Furthermore, microwave radiated from the high-power wireless facilities or communication/electric system **501** can be removed. Moreover, after collecting microwave, the collected microwave may be converted into electric energy and then stored, or may be immediately supplied to other equipment as an energy source.

[0070] In the antenna array arrangement method, as illustrated in FIG. **5**, antennas are arranged on all sides in order to completely shield EMI generated in the system. In this manner, leaking noises can be reduced, and energy can be reproduced by using EMI leaking from the system.

Fifth Embodiment

[0071] FIG. **6** is a conceptual diagram explaining an energy harvesting apparatus using microwave energy radiated from side lobes among microwaves radiated from a general antenna in accordance with a fifth embodiment of the present invention.

[0072] The fifth embodiment of the present invention is directed to providing a method for reproducing electric energy by using energy corresponding to side lobes among radiation patterns in order to control and shield microwave radiated from the communication/broadcast repeater and the base station to other areas.

[0073] In this embodiment, an energy collecting antenna **603** is installed in the rear side of the communication/broadcast antenna **601** or the region belonging to the side lobes. The installation of the energy collecting antenna **603** makes it possible to obtain energy by using microwave unnecessary to communication. The receiving energy can be increased by implementing the energy collecting antenna **603** in an array antenna type. A reproduction unit (not shown) may be provided for converting the collected energy into an electric form and then storing energy, and the energy stored in an electric condenser (not shown) can be used.

[0074] Moreover, the radiation direction of the communication/broadcast antenna **601** can be stabilized by adjusting the position and angle of the energy collecting antenna **603**. That is, the energy collecting antenna **603** is installed at the position corresponding to the side lobes among the radiation patterns of the communication/broadcast antenna **601**, considering the angle of the energy collecting antenna **603**. By installing the energy collecting antenna **603** in the above-described manner, microwave radiated to other areas is blocked. Thus, the interference problem can be solved, and the energy can be harvested.

[0075] The energy harvesting apparatus in accordance with the embodiments of the present invention can ensure a stable energy source, solve energy harvesting limitation caused by existence of variable parameters and so on, and reduce influence of microwave on a human body.

[0076] While the present invention has been described with respect to the specific embodiments, it will be apparent to those skilled in the art that various changes and modifications may be made without departing from the spirit and scope of the invention as defined in the following claims.

What is claimed is:

1. An apparatus for harvesting energy from a microwave in an electricity storage system of a building, the apparatus comprising:

a plurality of rectennas arranged with a predetermined length according to characteristic of microwave to be absorbed, and configured to collect microwave in the atmosphere and convert the collected microwave into electric energy;

a current converter configured to convert the electric energy outputted from the rectennas into a storable current; and

a charging tank configured to store the current outputted from the current converter,

wherein the arranged rectennas are attached to an outer wall of the building, and the rectennas attached to the top of the building are printed in a transparent conductor on the surface of a solar cell.

2. The apparatus of claim **1**, further comprising a wind power generator configured to generate induced electricity by using wind power and provide the induced electricity to the charging tank.

3. The apparatus of claim **1**, further comprising a plurality of rectennas configured to collect microwave generated from a device generating microwave inside the building, convert the collected microwave into an electric current, and provide the electric current to the current converter.

4. The apparatus of claim **3**, wherein the rectennas are printed on a transparent conductor in array type, and four sides of the device generating the microwave are shielded by the rectennas, thereby preventing leakage of the microwave.

5. The apparatus of claim **1**, wherein, in case where a mobile communication repeater or a broadcast repeater is installed in the outside or top of the building, the apparatus further comprises a plurality of array rectennas configured to prevent microwaves generated at the mobile communication repeater or the broadcast repeater from flowing into the building, and to convert the microwave generated at the mobile communication repeater or the broadcast repeater into electric energy.

6. A system for harvesting energy from a microwave in an electricity storage system, the system comprising:

a plurality of rectennas having a predetermined length and configured to collect a magnetic field among microwaves radiated from a high voltage cable and convert the collected magnetic field into electric energy;

a current converter configured to convert the electric energy outputted from the rectennas into a storable current; and

a charging tank configured to store the converted current,

wherein the rectennas are spaced apart from the high voltage cable by a predetermined distance and arranged in a form of a fence so that a magnetic field does not affect a human body.

7. The system of claim **6**, wherein the fence is made of a transparent conductor, and the array rectennas are printed on the fence.

8. The system of claim **6**, wherein the fence is configured in a resonance structure or an electromagnetic induction structure.

9. The system of claim **6**, wherein, in case where a mobile communication repeater or a broadcast repeater is installed in the outside or top of the building near the electricity storage system, the system further comprises a plurality of array rectennas configured to collect a microwave generated from the mobile communication repeater or the broadcast repeater and convert the collected microwave into electric energy.

10. The system of claim **9**, wherein the array rectennas are spaced apart by a predetermined distance and arranged in a form of a fence so that the microwave does not affect a human body.

11. An apparatus for harvesting energy from a microwave radiated from a system with an antenna, the apparatus comprising:

a plurality of rectennas configured to absorb a microwave radiated in an unwanted direction among microwaves radiated from the antenna and convert the absorbed microwave into electric energy;

a current converter configured to convert the electric energy outputted from the rectennas into a storable current, and

a charging tank configured to store the current outputted from the current converter,

wherein the rectennas are spaced apart from the antenna by a predetermined distance in the unwanted direction and arranged in a certain form to shield the microwave.

12. The apparatus of claim **11**, wherein, when the antenna is a parabolic antenna, the rectennas are arranged on a rear plate of the parabolic antenna to absorb a microwave radiated in a rear direction among microwaves radiated from the parabolic antenna and convert the absorbed microwave into electric energy.

13. The apparatus of claim **12**, wherein the rectennas are implemented on a transparent conductor by using a printing scheme.

14. The apparatus of claim **11**, wherein, when the antenna is a dipole antenna, the rectennas are arranged to absorb a microwave radiated in an unwanted direction among microwaves radiated from the antenna and convert the absorbed microwave into electric energy.

15. The apparatus of claim **14**, wherein the rectennas are implemented on a transparent conductor by using a printing scheme.

(57) ABSTRACT

Methods and apparatus for control of DC-DC converters. The DC-DC converter is operable so that the low side supply switch may be inhibited from turning on in a cycle following the high side supply switch turning off. Turn on of the low side switch is inhibited if the time between turn off of the high side switch and the inductor (L) current reaching zero is less than a predetermined duration. Inhibiting the low side switch from turning on can prevent the inductor current from going negative, which would reduce the efficiency of the converter. When turn on of the low side switch is inhibited the inductor current flows through a parallel path, such as a parasitic body diode associated with the low side switch, which allows current flow in one direction only.

DC-DC CONVERTERS

[0001] This application claims the benefit of U.S. Provisional Application No. 61/228,002, filed Jul. 23, 2009, and U.S. Provisional Application No. 61/261,123, filed Nov. 13, 2009.

BACKGROUND OF THE INVENTION

[0002] 1. Field of the Invention

[0003] This invention relates to voltage converters, especially to DC-DC or switched voltage regulators and to methods and apparatus for control of such regulators.

[0004] 2. Description of the Related Art

[0005] In electronic equipment in general, and particularly for fast moving segments such as portable consumer devices such as mobile phones, MP3 players etc, there is a relentless push to use the latest processor technology to increase the device capability and feature set while reducing power and cost. As the next generation of processors start to become available, they need to operate from lower voltages than previous generation processors so as to allow use of the reduction in process feature size, i.e. W/L, that enables a greater level of integration such that it is beneficial in terms of reduced die size, reduced die cost and reduced power consumption. Typically such processors are powered via a DC-DC voltage converter which provides a regulated voltage to the processor.

[0006] These trends result in two design challenges for DC-DC converters to service these applications: one induced by the choice of the value of the low voltage; the other by battery technology lagging behind the change to lower processor supply voltages.

> **[0007]** (i) The reduction in processor supply voltage requires a much tighter control—in absolute terms—of the DC-DC converter output voltage under all prevailing processor load and battery conditions. If the control over the processor supply voltage is not sufficient, problems with under or overvoltage may occur: both equally undesirable.
>
> **[0008]** (ii) Since the battery terminal voltage has not dropped appreciably, and the duty cycle of a DC-DC converter is given by the ratio of V_{OUT}/V_{IN}, duty cycles must therefore reduce. This, coupled with the desire for small external components pushes the DC-DC converter to high operating frequencies, resulting in extremely short switch on i.e. conduction, times. The increase in switching speed afforded by the reduction in transistor feature size is not normally available for the power switches since the interface components must be rated to battery voltage.

[0009] Since small conduction periods, i.e. on times, of the power switches are difficult to control, it is becoming increasingly difficult to control the lower processor output voltages with adequate accuracy using traditional Peak Current Mode control methods. Valley Current Mode (VCM) is an alternative method of control of a DC-DC converter which has been proposed. This method of DC-DC loop control controls the input transistor off, i.e. non-conduction, time, rather than the on time. For the low duty cycle required, the non-conduction time is longer than the conduction time, so is therefore easier to control. Also VCM is known to offer an inherently higher bandwidth and an improved transient response.

SUMMARY OF THE INVENTION

[0010] It is therefore an aim of the present invention to provide improved control of DC-DC converters.

[0011] Thus according to the present invention there is provided a DC-DC converter comprising: an inductor operably connected between a first node and an output node; a high side switch operably connected between a high side supply input node and the first node; a low side switch operably connected between a low side supply input node and the first node; switch control circuitry for controlling said switches, wherein the switch control circuitry comprises first monitoring circuitry for determining whether a first time period between the high side switch turning off and the inductor current reaching zero is less than a threshold time period, wherein if the first time period in one duty cycle is less than the threshold time period the switch control circuitry inhibits the low side switch from turning on in a subsequent cycle.

[0012] The DC-DC converter of this aspect of the invention thus has an inductor connected to a first node connected between high and low side supply switches. The high and low side supply switches are any suitable switches, such as power switches, for example PMOS and NMOS switches respectively, for connecting, in use, to high and low side supplies, e.g. a voltage input V_{IN} and ground.

[0013] As the skilled person will appreciate in operation the first node, i.e. the input node for the inductor, is typically switched between the high side supply and the low side supply in a duty cycle determined by the input and output voltages. The inductor current rises during the period that the high side switch is turned on, the low side switch being turned off during this period, and falls during the period where the low side switch is turned on, the high side switch being turned off during this period.

[0014] In current mode control a signal representing the inductor current is compared with a threshold derived from the voltage output of the converter to control the duty cycle. As the skilled person will appreciate one or more additional signals, for instance a slope compensation ramp signal, may be added to one or both of the current or voltage signals prior to comparison.

[0015] The converter may be controlled in a peak current mode, where the current is measured during the period when the high side switch is on and the comparison determines when the low side switch turns on, i.e. the switching occurs at the peak current. Alternatively the converter may be controlled in a valley current mode, where the current is measured during the period when the low side switch is on (and hence is decreasing) and the comparison determines when the high side switch turns on, i.e. the switching occurs at the valley current.

[0016] In either mode of control, when the low side switch is turned on, the current in the inductor drops steadily until the low side switch turns off—which could be due to the end of the cycle in Peak Mode control or the appropriate Valley current being reached in valley mode control. In some operating conditions however, at relatively low load current demand, the inductor current would drop to zero and then go negative, i.e. the direction of current flow would reverse, before the high side switch was turned on. This reversal of current in the inductor means that current would be flowing away from the load (i.e. away from an output capacitor) and to the low side supply. This is inefficient as charge previously supplied during via the high side supply is effectively wasted.

[0017] In some converters therefore there may be circuitry to prevent the low side switch from passing a significant negative current. This circuitry may involve monitoring the current flow through the low side switch and/or inductor in order to turn the switch off before a significant reverse current can flow. Typically however there will be propagation delays associated with such monitoring circuitry as will be described in detail later and hence there will be a minimum conduction period for the low side switch. In other words when the low side switch is turned on it will be on for at least this minimum conduction period before it is turned off.

[0018] At low current demands the inductor current may be low enough such that the low side switch being turned even on for the minimum conduction period would result in a reverse current flow.

[0019] According to this aspect of the present invention therefore the first monitoring circuitry determines whether a first time period between the high side switch turning off and the inductor current reaching zero is less than a threshold time period. This threshold time period is set to be greater than the minimum conduction period mentioned above. If the inductor current does decay to zero in a period less than this time threshold period the low side switch is inhibited from turning on in a subsequent cycle.

[0020] Operation of the high side switch is not affected and thus the high side switch may be turned on as appropriate in accordance with the mode of control. However the low side switch would remain off when the high side switch is subsequently turned off.

[0021] As will be described in detail later, if one of the high or low side switches is turned off, and the other switch is not turned on, at a point when there is current flow in the inductor then current may continue to flow through a parallel path. For example the current may flow through an NMOS body diode associated with a NMOS power switch. As will be explained later in more detail an NMOS power switch will usually have a parasitic diode associated with it. When the NMOS power switch is turned on the parasitic diode will have virtually no effect. However if the NMOS switch is turned off and the high side switch is also turned off, any current flowing in the inductor may flow through the NMOS body diode. As is usual with a diode the current flow is substantially in one direction only and hence this current will not reverse. Thus by allowing the current to flow through the NMOS body diode the inductor current can decay to zero but it will not go negative, i.e. the direction of current flow will not reverse. This mode of operation therefore prevents the inductor current from going substantially negative.

[0022] Instead of relying on an inherent body diode associated with the low side switch, in some embodiments a separate diode (or other unidirectional current device) may be specifically provided in parallel with the low side switch to provide a parallel path and control current flow when the low side switch is off. The separate diode should be arranged to allow forward current to flow if the low side switch is turned off (before the high side switch is turned on) but to prevent current reversal in the inductor. Any suitable diode, such as a low drop diode or Schottky diode could be used.

[0023] As mentioned, if, in one cycle, the first time period between the high side switch turning off and the inductor current reaching zero is less than a threshold time period, then the low side switch is inhibited from turning on in a subsequent cycle. The low side switch may be prevented from turning on in the very next cycle but, if the converter has switched to a pulse skip mode of operation the low side switch would not be turned on anyway. As will be described in more detail later in some instances the converter may operate in a mode, termed a pulse skip mode, where the high side switch is not turned on during a particular cycle. In pulse skip mode the low side switch is also kept turned off. There may therefore be one or more cycles in which in the high side switch, and hence the low side switch, are not turned on.

[0024] Preferably, if the time period between the high side switch turning off and the inductor current reaching zero is less than the time threshold period but the converter then enters pulse skip mode (thus skipping the turn on of the high side switch and hence the low side switch in one or more cycles), the inhibition of the low side switch is maintained until the converter exits pulse skip mode. In other words, even if there have been one or more cycles in which the high side switch has not turned on, the next time that the high side switch is turned on the low side switch is subsequently inhibited from turning on. The subsequent cycle (in which turn on of the low side switch is inhibited) is therefore preferably the next one in which the low side switch would otherwise turn on following the high side switch turning off.

[0025] It will be appreciated that the term cycle refers to a switching cycle wherein, in non pulse skip mode of operation and where turn on of the switches is not inhibited, each of the high side and low side switches will be on for a period of time. In embodiments of the present invention the cycle is defined by a clock signal. An appropriate edge of a clock pulse, i.e. the leading or trailing edge is used to start a cycle and the same edge of a subsequent pulse is used to define the start of the next cycle (and hence the end of the present cycle). Such DC-DC converters allow constant frequency operation as fixed by the clock signal.

[0026] DC-DC converters allowing constant frequency operation offer several advantages as compared to other modes of operation, such as constant on-time converters where the frequency of operation is variable. Operating at a constant frequency means that the frequency of operation is known in advance and the designer of the device that uses the DC-DC converter can take this into account. Thus interference due to the switching frequency of the DC-DC converter can be avoided and line filters or notch filters and the like can be designed and used in the device with a knowledge of the switching frequencies to reduce interference. Further in a device with several constant frequency DC-DC converters the clock signals for the converters may be phased to reduce the total combined input current ripple, i.e. to arrange the high side on time of one converter to occur during, or at least overlap with, the high side off time of another converter. This can reduce the stress on the supply input capacitor and the peak current requirements of the common supply.

[0027] In a preferred embodiment of the present invention therefore the converter is one where the switching cycle is defined by clock edges of a clock signal. The skilled person will of course appreciate that the converter may be designed to operate at more than one different switching frequency and an appropriate frequency may be selected in use by selecting an appropriate clock signal. For example a converter may be operable at a first fixed frequency based on a first clock signal or a second fixed frequency based on a second clock signal. This allows the converter to balance efficiency against transient performance. As the skilled person will be aware higher switching frequencies mean more switching losses but generally better transient performance. At lower current loads, transient performance may be less of an issue and the frequency may be switched to a lower frequency clock signal to improve efficiency. In any case however the possible frequencies of operation are known in advance and fixed by the first and second clock signals and are not continually variable according to small changes in load.

[0028] The skilled person will also appreciate that it is common to apply small amounts of dither to a clock signal to vary the switching frequency slightly. This is a known change however which is achieved (generally) though prearranged variation of the clock signal. Again the device designed will be aware of the degree of dither that will be applied and the switching frequency will be maintained within a small set range defined by the amount of dither. As used in this specification the term constant frequency applied to switching frequencies shall be taken to mean that the switching cycle is controlled based on clock edges of a clock signal, including clock signals that are dithered.

[0029] In a peak current mode converter the turn on of the high side switch is controlled based on the relevant clock edge. Thus at the start of the cycle the high side switch is turned on unless the converter is in pulse skip mode in which case both switches remain off for the entire cycle. Once turned on, the high side switch is subsequently turned off based on a comparison of the current signal with the voltage error (plus any slope compensation). At this point the low side switch is turned on, unless inhibited from doing so, and in any case the time until the inductor current reaches zero is compared to the time threshold period.

[0030] In a valley current mode converter the clock edge controls turn on of the low side switch. Assuming that the high side switch was turned on in the previous cycle (i.e. the converter was not in pulse skip mode) the start of the cycle sees the low side switch turn on, unless the low side switch is inhibited from doing so. In either case the time between the high side switch turning off (i.e. end of the previous cycle) and the inductor current reaching zero is compared to the time threshold period. Turn on of the high side switch is based on a comparison of the current signal with the voltage error (plus any slope compensation).

[0031] As briefly mentioned above and as will be explained in detail later, when a low side switch, such as a NMOS switch, is turned off, when current is still flowing in the inductor (as there would be when the high side switch has just been turned off), current will still flow through a parallel path. For instance the current may flow through a parasitic body diode associated with the NMOS switch. The inductor current will still therefore flow and will decrease (faster than it would have done had the switch been on) until the inductor current reaches zero. The parasitic diode will not conduct in the reverse direction however and thus there will be no reverse current and hence no efficiency loss. In some embodiments a separate diode may be provided to provide the parallel path and to provide forward conduction only when the low side switch is off and the high side switch has not turned on.

[0032] If a DC-DC converter according to this aspect of the invention is operating normally and the current load drops (for constant output voltage) the inductor current will reach zero earlier and earlier in each cycle. Were the demand to continue to fall at some point the inductor current will reach zero in a time period less than the time threshold period. The duration of time threshold period is chosen in view of an expected maximum cycle-to-cycle change for the particular converter such that the inductor current in the cycle in which the time threshold period is reached will not have undergone any significant reversal. As mentioned above there is a practical minimum conduction period for the low side switch. If the ideal on-time for the low side switch drops below the minimum conduction period it is not possible to turn the low side switch off in time and current reversal may occur. The time threshold period is chosen to be sufficiently larger than the minimum conduction period such that the converter is unlikely to have a low side switch on-time in one cycle which is greater than the time threshold period but which, in the very next cycle, has an ideal low side switch on-time which is shorter than the minimum conduction period.

[0033] When the inductor current reaches zero (from the high side switch turning off) in a time period shorter than the threshold time period this is indicative that, were the current drop to continue, current reversal would be likely. The low side switch is therefore inhibited from turning on in a subsequent cycle to avoid the potential for current reversal. This embodiment of the present invention therefore effectively pre-emptively prevents a situation where current reversal could occur.

[0034] The cycle in which the low side switch is inhibited from turning on may be the very next cycle but, as mentioned above, in some converters there may be a pulse skip mode where the high side switch is not turned on in every cycle, depending on the loading. Clearly if the high side switch is not turned on the low side switch need not be turned on either. However current reversal is still a possibility were the low side switch to turn on immediately after the next high side switch conduction period. Therefore the switch control circuitry is arranged to inhibit the low side switch from turning on following the next time that the high side switch has been on, i.e. in the next non pulse skip cycle.

[0035] The converter operates in this mode, inhibiting turn on of the low side switch in a subsequent cycle for as long as the inductor current reaches zero before the time threshold. Only when the operating conditions change, and the inductor current reaches zero after the time threshold period does normal operation resume, with the low side switch turning on when the high side switch turns off.

[0036] As mentioned it can be beneficial for efficiency reasons to prevent the inductor current from going negative, i.e. flowing away from the load during the duty cycle. The switch control circuitry may therefore be operable, in a cycle where turn on of the low side switch is not inhibited, to turn the low side switch off before the high side switch is turned on. This means that there may be a period in the duty cycle where both of the high and low side switches are off. This may be referred to as a discontinuous switching mode as there is a discontinuity in the operation of the switches. The switch control circuitry may comprise second monitoring circuitry for determining the current flow in the inductor from the electrical properties of the low side switch when the low side switch is on and monitoring current flow in the inductor against a current threshold and wherein the switch control circuitry is arranged to turn the low side power switch off when the current threshold is reached.

[0037] The current flowing through the low side switch, and hence through the inductor, can be determined by the electrical properties of the low side switch when it is turned on. For a transistor switch, such as an NMOS switch, the source-drain voltage of the transistor is proportional to the current flow through the channel. By using the electrical properties of the low side switch to derive the inductor current no additional sense resistor is required. As will be appreciated the use of sense resistors purely to allow sensing of the inductor current would introduce associated resistive losses and hence inefficiency into the operation of the converter.

[0038] By setting the low side switch to turn off when the inductor current reaches a threshold current level at least some of the period of negative, or reverse, inductor current flow may be prevented. The threshold may be set at zero current but propagation delays and the like mean that there would be a delay between the inductor current reaching the threshold and the low side switch actually being turned off. During this time the inductor current may have decreased further, i.e. a reverse current flow may have started. The threshold is therefore preferably set to a positive level such that the low side switch is turned off before the current flow in the inductor reverses direction. Preferably the threshold level is set as low as possible allowing for voltage offsets and propagation delays to ensure that the inductor current does not reverse direction. However a small current reversal may be tolerated in some applications. The threshold level may be fixed or may be configurable and may be changed in operation depending on the operating conditions of the converter, such as the target output voltage.

[0039] The first monitoring circuitry, i.e. the circuitry for monitoring whether the inductor current reaches zero before the time threshold period, may comprise a voltage threshold monitoring circuit for comparing the voltage of the first node with a threshold voltage when the low side switch is turned off. When low side switch is turned off and an inductor current is flowing, as mentioned above there will be conduction through a parallel path such as a unidirectional switch associated with the low side switch. The first node will therefore be at a diode voltage below the low side supply, e.g. ground at this point. Once the inductor current extinguishes the node will fly high. Thus detecting the voltage on this node crossing a voltage threshold can be used to determine when the inductor current has reached zero. The voltage threshold may be set to zero volts.

[0040] Various arrangements for the first monitoring circuitry exist. The first monitoring circuitry may for instance comprise a first timer circuit configured, in response to the high side switch turning off, to generate a first output signal for a period equal to the time threshold period and thereafter to generate a second output signal. For example the timer circuit may have a logic high or logic low output. If the output is logic high, for example, the time threshold period has not expired. Thus the monitoring circuit may comprise a simple logic arrangement. If the inductor current reaches zero, e.g. the output of voltage threshold monitoring circuit goes high, when the output of the timer circuit is also high, an inhibit low switch signal is generated. This could easily be implemented by an AND gate arrangement although many other options exist as will be appreciated by the skilled person. In an alternative arrangement the first monitoring circuitry may comprise a first timer circuit configured to determine whether the inductor current has reached zero at a time equal to the time threshold period after the high side switch turns off, i.e. in order words the inductor current is sampled at a time equal to the first time period after the high side switch turns off.

[0041] The first timer circuit may be arranged to receive a control signal synchronous with a high side switch control signal (e.g. a copy of the high side switch control signal or feedback from the switch driver) and delay said control signal by at least one delay equal to the threshold time period using a delay element. The period between receipt of the control signal and receipt of the delayed control signal can be used to determine the first time threshold period. Other timer arrangements are possible however. A ramp signal could be generated which reaches a threshold at the end of the time threshold time period. A counter could count the cycles of a sufficiently fast clock signal.

[0042] The first timer circuit may alternatively be arranged to receive a low side control signal synchronous with a low side control signal (e.g. a copy of the low side switch control signal or feedback from the switch driver) and delay said low side control signal by at least one delay such that the time period between the high side switch turning off and the delayed low side control signal is substantially equal to the time threshold period. It will be appreciated that the low side switch will turn on (if not inhibited from doing so) a short time after the high side switch turns off. Hence the delay applied to a low side control signal may be slightly shorter than the threshold time period as there will be some inherent delay in low side switch turning on after the low side switch turns off.

[0043] It will be clear however that the time period between the time at which the low side switch turns on (or would otherwise turn on if not inhibited from doing so) and the inductor current reaching zero may be monitored as a way of monitoring the time between the high side switch turning off and the inductor current reaching zero. There is a generally fixed delay between the time at which the high side switch turns off and the time at which the low side switch turns on (or would otherwise turn on if not inhibited from doing so).

[0044] The time threshold period may be fixed or may be configurable. The period may be configurable, i.e. different time threshold periods may be chosen, to cope with different operating conditions.

[0045] The low side switch may be an NMOS transistor and the high side switch may be a PMOS transistor.

[0046] The DC-DC converter, in some embodiments, may be operable in valley mode control. The converter may comprise circuitry for keeping a current feedback loop active when the low side switch is off. The circuitry for keeping a current feedback loop active when the low side switch is off comprises emulation circuitry for emulating the change in inductor current when the low side switch is off.

[0047] As will be appreciated valley mode control uses the current in the inductor during the period when the low side switch is off to control switching. However this aspect of the present invention inhibits turn on of the low side switch in certain circumstances. In valley mode control, when the low side switch is turned off, current mode control of the converter may be difficult to achieve. This embodiment of the present invention therefore comprises emulation circuitry for emulating the change in inductor current during a period when both the high side and low side switches are turned off. The emulated change in inductor current can be used by the switch control circuitry to control when to turn on the high side switch.

[0048] The switch control circuitry may comprise current sense circuitry for determining the current flow in the inductor from the electrical properties of the low side switch when the low side switch is turned on and wherein the output of said current sense circuit comprises the first signal when the low side switch is turned on. This provides a lossless current mode control. However when the low side switch is off the electrical properties of the switch can no longer be used to derive the inductor current. The emulation circuit however emulates the change of inductor current when the low side switch is turned off and hence the emulated change in current can be used when the low side switch is off. This embodiment of the present invention therefore allows lossless current sensing but maintains control of the current loop when the low side switch is off.

[0049] In some embodiments the DC-DC converter may be operable in peak mode control.

[0050] The switch control circuitry may be operable in a pulse skip mode to prevent turning the high side switch on in a cycle. As mentioned above, at low operating current it may be advantageous to skip pulses, i.e. not turn the high side switch on in certain cycles.

[0051] Where the converter is operable in valley mode control the switch control circuitry may prevent turning the high side switch on in a cycle if a second time period between turning the high side switch on and turning the high side switch off would be less than a second threshold time period. This embodiment of the present invention implements a pulse skip mode based on a minimum high side conduction time.

[0052] The switch control circuitry may comprise a second timer circuit for producing an inhibit signal which inhibits turn on of the high side switch, for a time period substantially equal to the second time threshold period, before a clock edge which would cause the high side switch to turn off. The second timer circuit may comprise an input for receiving an input clock signal, a delay for producing a delayed clock signal and circuitry for generating the inhibit signal based on the input clock signal.

[0053] In one embodiment of DC-DC converter the cycle frequency of the converter is constant. However the embodiments of the present invention are applicable to variable frequency converters and/or converters that apply dither to the clock edges.

[0054] The DC-DC converter according to these embodiments of the invention therefore provide a converter that can be controlled to low load current demand and which offers high efficiency. Consider a buck converter, with an inductor switched between a supply VIN and Ground by a PMOS and an NMOS transistor respectively. Under high or medium current demand, the inductor current, composed of an average component and a ripple, remains above zero through every cycle. This is termed Continuous Conduction Mode (CCM). As the load current demand decreases, it is advantageous for efficiency reasons to alter the control so that the current in the inductor goes to zero for some of each cycle to avoid ripple being large enough to cause a reverse in the current in the inductor. This is termed Discontinuous Current Mode (DCM). At even lower load currents it is advantageous to “pulse-skip” so the PMOS switch does not recharge the inductor in some cycles, but this can lead to undesired behaviour.

[0055] These various modes present different control problems and dynamics, and it is important to be able to transition between modes seamlessly without transients appearing during change over. This aspect of the present invention provides a control mechanism that achieves these efficiency benefits and maintains control over the current loop of the converter.

[0056] In another aspect of the present invention there is provided a method of controlling a DC-DC converter comprising an inductor operably connected between a first node and an output node; a high side switch operably connected between a high side supply input node and the first node; and a low side switch operably connected between a low side supply input node and the first node; the method comprising: monitoring whether a first time period between the high side switch turning off and the inductor current reaching zero is less than a threshold time period, and where the first time period in one duty cycle is less than the threshold time period the switch control circuitry inhibiting the low side switch from turning on in a subsequent cycle.

[0057] This method of the present invention offers all of the same advantages and can be used in all of the same embodiments as described with reference to the first aspect of the invention.

[0058] In another aspect of the invention there is provided a DC-DC converter comprising: a PMOS switch operably connected between a voltage input node and the first node; an NMOS switch operably connected between a ground input node and the first node; control circuitry operable to control said switches, wherein the switch control circuitry detects whether a first time period between the PMOS switch turning off and the voltage at the first node reaching zero is less than a time threshold, wherein if the first time period is less than the threshold time period the switch control circuitry prevents the NMOS switch from turning on in the next cycle.

[0059] In a further aspect of the invention there is provided a DC-DC converter comprising: an inductor operably connected between a first node and an output node; a high side switch operably connected between a high side supply input node and the first node; a low side switch operably connected between a low side supply input node and the first node; switch control circuitry arranged to monitor the time between the high side switch turning off and the voltage at the first node reaching zero and, if said monitored time is less than a first time threshold, preventing the low side switch from subsequently turning on the next time the high side switch is turned on.

[0060] The invention, in another aspect, provides a DC-DC converter comprising: an inductor operably connected between a first node and an output node; a high side switch operably connected between a high side supply input node and the first node; a low side switch operably connected between a low side supply input node and the first node; and switch control circuitry operable in a first mode where the low side switch is not turned on following the high side switch being turned off.

[0061] A further aspect of the invention provides a DC-DC converter operable in a mode wherein a low side switch is not turned on following activation and deactivation of a high side supply switch.

[0062] In general the problem of NMOS current reversal in light loading is mitigated by detecting if the output voltage crosses zero before a time threshold that is longer than the minimum NMOS on time set by the propagation delay from the zero-current comparator, and if so, disabling the NMOS in the next cycle. The advantage is that valley mode control is maintained down to very light loads and the efficiency is only sacrificed when direct NMOS control is no longer possible. The diode mode of operation could also occur in non-pulse-skipping mode, say in DCM with a very short PMOS on-time and a high V_{OUT} relative to V_{IN}-V_{OUT} giving a fast NMOS current slew rate, giving power dissipation savings.

[0063] Conveniently the output voltage of the NMOS switch is used to determine the zero crossing time. In general however this aspect of the invention relates to means of preventing current reversal and especially to circuitry for determining a forward current duration for the NMOS and for preventing the NMOS from turning on in the subsequent cycle if the forward current duration is less than a first duration. Such means may include a sense resistor for sensing the inductor current and/or a current transformer.

[0064] The present invention provides a practical Valley Current Mode converter that can be used, with current mode control, for a variety of applications. Embodiments of the present invention realise an integrated circuit (IC) arrangement and in particular a power management integrated circuit (PMIC) arrangement comprising a Valley Current Mode converter. An embodiment of the Valley Mode converter comprises a fixed frequency valley mode converter, i.e. a converter having a switching frequency which is based on a predetermined clock signal. The Valley Current Mode converter may be operable in Continuous Current Mode (CCM), Discontinuous Current Mode (DCM) and/or a transitional phase between DCM and CCM. The valley mode converter may comprise a valley mode converter operable in a pulse skip mode. The valley current mode converter may be controlled based on the same control loop in all of these modes of operation, i.e. the loop that provides control in CCM also provides control in DCM.

[0065] Embodiments of the invention provide current mode converters, especially valley current mode converters, with lossless current sensing. Lossless sensing techniques avoid the use of separate sense resistors with the associated losses. Preferably the converter is fully integrated in that the high and low side switches are integrated within an IC/PMIC in addition to the converter and the internal (preferably lossless) current sense circuits. A fully integrated lossless valley current mode converter represents a novel embodiment of switched converter. Preferably the lossless and/or fully integrated converter is operable at a fixed switching frequency. A converter comprising lossless sensing and enabling CCM and DCM operation is thus provided by the present invention and a novel IC/PMIC may comprise such a converter.

[0066] The ability to operate at a fixed frequency is a particular advantage of the embodiments of the present invention and in general one aspect of the invention relates to a fixed frequency converter which is operable in non-CCM modes of operation, whether full DCM and/or a transitional phase between CCM and full DCM and/or a pulse skip mode of operation.

[0067] The various aspects of the present invention are described principally with reference to buck converters but other embodiments of the invention provide boost converters or buck-boost converters.

[0068] Although described above in relation to DC-DC converters the embodiments of the invention can be applied generally to switching regulators. All aspects of the invention may be implemented in a power management apparatus such as a power management integrated circuit. The embodiments of the present invention are applicable to use in electronic devices and in particular to portable devices.

BRIEF DESCRIPTION OF THE DRAWINGS

[0069] The invention will now be described by way of example only with reference to the following drawings, of which:

[0070] FIG. **1** shows a typical arrangement of a DC-DC converter arranged to power processor circuitry;

[0071] FIG. **2** illustrates a conventional DC-DC converter;

[0072] FIG. **3** illustrates the parasitic diodes associated with the switches of the output stage;

[0073] FIG. **4** shows inductor current and voltage waveforms at a certain level of current demand;

[0074] FIG. **5** shows a DC-DC converter according to an embodiment of the invention;

[0075] FIG. **6** shows inductor current and voltage waveforms in a DC-DC converter according to an embodiment of the invention at a level of current demand lower than that shown in FIG. **4**;

[0076] FIG. **7** shows inductor current and voltage waveforms in a DC-DC converter according to an embodiment of the invention at a level of current demand lower than that shown in FIG. **6**;

[0077] FIG. **8** shows inductor current and voltage waveforms between cycles;

[0078] FIG. **9** shows current and voltage waveforms illustrating a mode of operation at low current demand;

[0079] FIG. **10***a* illustrates various control waveforms of an embodiment of a DC-DC Converter operating in DCM;

[0080] FIG. **10***b* illustrates various control waveforms of an embodiment of a DC-DC Converter operating in a transitional mode between CCM and DCM;

[0081] FIG. **11** illustrates the relative efficiency of operating a DC-DC in modes according to embodiments of the invention as compared to Forced CCM;

[0082] FIG. **12** illustrates one embodiment of a current sense circuit;

[0083] FIG. **13** illustrates one embodiment of a ramp generator capable of emulating a change in inductor current;

[0084] FIG. **14** illustrates a simplified embodiment of a duty modulator;

[0085] FIG. **15** illustrates one embodiment of a circuit arrangement for implementing diode mode of operation; and

[0086] FIG. **16** illustrates one embodiment of a circuit arrangement for implementing pulse skip operation.

DETAILED DESCRIPTION

[0087] FIG. **1** shows a typical application where processor circuitry **101**, which may, for example, be a processor of a portable electronic device **107**, is supplied with a voltage V_{OUT} **102** by a DC-DC converter **100**. The DC-DC converter **100** receives an input voltage V_{IN} **103** and an external clock signal CLK **104** and outputs the required voltage output V_{OUT} **102**. It is usual for the supply voltage of a processor to be reduced when the processor is idling in order to save power, and then to ramp up to a more normal operating voltage where the processor may achieve full operating speed. The processor circuitry **101** therefore provides voltage select signals V_{SEL} **105** to the DC-DC converter **100** to select an appropriate voltage output V_{OUT}. The voltage select signals may be digital signals for controlling a programmable element of the DC-DC converter, such as a level shifter, as will be described later. The DC-DC converter **100** may also be operable in various modes, as will be described later, and the processor circuitry may select a particular mode of operation by appropriate mode control signals MODE **106**. It will be appreciated that DC-DC converters may be used to provide power to device sub-systems other than processors and the embodiments described herein are generally applicable to many DC-DC converters or switched voltage regulators used for many applications.

[0088] A conventional current-mode buck (i.e. step down) DC-DC converter **200** is shown in simplified form in FIG. **2**. The converter **200** comprises two nested feedback loops, an inner Current Control loop and an outer Voltage Control loop.

[0089] The Current Control loop block **201** takes an input signal V_{ERROR} and a current sense signal ISNS fed back from the output stage and generates pulse-width modulated drive signals for the output stage **202**. The voltage on the output stage output node LX is switched between ground and supply, V_{IN}, at a controlled duty cycle, resulting in a triangular current waveform in the inductor L. The inductor L and output capacitor C1 act as a filter to ensure an average voltage V_{OUT} at an output node **203**.

[0090] In operation the inductor current is sensed, and compared with V_{ERROR}. So this feedback loop generates an output sensed current varying according to the input signal V_{ERROR}. In many conventional DC-DC converters the sensed current is a peak current, although it is known to use an average current in some converters. In embodiments of the present invention to be described the minimum or "valley" current is used to control the duty cycle of the converter.

[0091] Variation of the delivered output current, smoothed by the output filter L, C**1**, modulates the output voltage at V_{OUT}. This voltage V_{OUT} is fed back, translated down to an appropriate voltage V_{OUT_LS} by a Level Shifter, or Voltage Shifter, block **204**, to the input of a Voltage Error Amplifier block **205**. The Voltage Error Amplifier block **205** compares this processed version of V_{OUT} with a supplied reference voltage V_{REF} and provides the error signal V_{ERROR} which drives the above described inner feedback loop to close the outer feedback loop and thus stabilise V_{OUT} at the desired voltage.

[0092] The Level Shifter **204** is illustrated as a resistive potential divider, but could be other voltage scaling or voltage-shifting circuitry, or even be a direct connection if the required V_{OUT} is equal to V_{REF}. The level shifter applies a conversion to the level of V_{OUT} such that, when V_{OUT} is equal to the desired or target output voltage, the level shifted signal V_{OUT_LS} has a known relationship to the reference voltage V_{REF} (e.g. the level shifted signal V_{OUT_LS} may be equal to V_{REF} when V_{OUT} is exactly the desired output voltage). The Level Shifter may be programmable, mechanically or digitally, to provide different voltage scaling or shifting circuitry, so as to allow the converter to be configurable to output different values of V_{OUT}. For instance, it may be programmable by a digital multi-bit signal, such as the VSEL signal generated by a processor as shown in FIG. **1**.

[0093] The Voltage Error Amplifier Block **205** is illustrated as including an Operational Transconductance Amplifier (OTA) **206** driving an RC network **207**, but could include some other amplifier. The RC network **207**, or other passive impedances, provide closed-loop stabilisation.

[0094] The Current Loop Control block **201** receives a signal **208** from the output stage **202** which passes through a Current Sensor Amp block **209** to pre-condition it, for instance to scale or strobe the signal, representative of the inductor current, to generate a convenient current sense signal ISNS. A duty modulator **210** compares the ISNS signal to the input V_{ERROR} to derive drive signals of the appropriate duty cycle to drive the output stage devices **10**, **20** on and off via a Switch Driver buffer stage **211**. The Duty Modulator may require a clock signal **212** and a Ramp Generator **213** to generate the necessary sequence of pulses as would be understood by one skilled in the art. Ramp Generator **213** may generate a slope compensation ramp signal which may be added, either in whole or in part, to the ISNS signal and/or the V_{ERROR} signal so as to prevent sub-harmonic oscillations as would be well understood by one skilled in the art.

[0095] The Output Stage **202** in general will have a high-side driver device such as a PMOS transistor **10** to switch the output to the high-side supply rail **214** (V_{IN}) and a low-side driver device such as an NMOS transistor **20** to switch the output to the low-side supply rail **215** (Ground). The Output Stage **202** is also required to supply information, i.e. an indication, of inductor current signal **208**, to feed back to the Current Control block **201**.

[0096] The inductor current could be sensed using a series resistor in series with the inductor or the respective transistor. However the use of such series resistors introduces an extra source of resistive power loss and thus reduces the efficiency of the converter. Efficiency is, especially for battery powered devices, an important consideration. It is preferable therefore to use "lossless" sensing techniques, for example to sense the drain-source voltage across the PMOS due to its on resistance. This gives a voltage proportional to the PMOS current.

[0097] In operation of a conventional peak mode DC-DC converter the PMOS switch is turned on at an edge of the clock signal **212**. In the lossless current sensing approach, i.e. in embodiments not having a sense resistor, the drain-source voltage of the PMOS is monitored to derive a current signal proportional to the current through the PMOS **10** and hence the inductor L. This current signal, appropriately scaled, is compared to the threshold V_{ERROR} signal. When the current reaches the threshold the PMOS is turned off by switch driver **211** and the NMOS is turned on, i.e. the switching occurs at the peak of the inductor current. Practically a slope compensation ramp signal is applied to either or both the current signal or V_{ERROR} signal prior to the comparison to prevent sub-harmonic oscillation. The effect is therefore that the current signal is compared with a threshold that ramps across each cycle.

[0098] The bandwidth of the current control loop is high, generating the appropriate pulse width on a cycle-by-cycle basis, whereas the bandwidth of the outer, voltage control, loop is relatively low, so the current loop may be analysed assuming a substantially static input voltage V_{ERROR}.

[0099] The terminal LX of the inductor L is switched to V_{IN} for a fraction D of each clock cycle and to ground for the remaining fraction 1-D of each cycle. The average voltage at node LX is thus D^*V_{IN}. The output capacitor C**1** is large enough for the voltage V_{OUT} to be substantially constant within each cycle, so the average voltage at V_{OUT} is also D^*V_{IN}. So for small V_{OUT} relative to V_{IN}, the duty cycle $D=V_{OUT}/V_{IN}$ may be small.

[0100] Also there is a push towards faster clocking frequencies to allow the use of lower value, physically smaller, inductors, which would further reduce the PMOS on-time, and the time available to sense its current.

[0101] As mentioned previously control of very short switching times is difficult. Some embodiments of the present invention therefore use Valley Current Mode (VCM) control. In VCM the NMOS switch **20** is turned on at a clock edge and the current in the inductor during the NMOS conduction period is monitored. When the inductor current drops to the V_{ERROR} threshold (as modified by the slope compensation ramp) the NMOS is turned off and the PMOS is turned on, i.e. the switching is controlled by the lowest inductor current or the valley current. For short duty cycles the NMOS switch may be turned on for significantly longer than the PMOS switch and so Valley Current Mode control can ease some aspects of control of a DC-DC converter at low voltages.

[0102] FIG. **4** illustrates the inductor current and the voltage at the output stage output terminal, LX, during one cycle of a set of repetitive cycles. The solid curves **1001** show waveforms for a higher average current, the dashed curves **1002** show waveforms for a lower current (assuming constant V_{IN} and V_{OUT}). The upper part of FIG. **4** shows the current curves at node LX and the lower part of the figure illustrates the voltages at node LX. During the first part of the illustrated cycle, i.e. between t_0 and t_1, the NMOS is conducting and LX is near ground while the other end of the inductor is kept at V_{OUT} by the output capacitor. The current therefore decreases at a slope $dI_L/dt=V_{OUT}/L$. During the second part of the cycle, i.e. between t_1 and t_2, the PMOS is conducting and the voltage of node LX is near supply, V_{IN}, while the other end of the inductor is kept at V_{OUT} by the output capacitor, so the current increases at a slope $dI_L/dt=(V_{IN}-V_{OUT})/L$. If the load current demand decreases the current waveform maintains substantially the same slopes, but moves downwards to reduce the average current supplied to the capacitor and eventually to the load, as illustrated by dashed curve **1002** representing a lower average current. As shown in the lower part of the FIG. **4**, the voltage at LX does not quite reach ground or V_{IN} while passing this current, due to the I.R drop of the conducting NMOS or PMOS. For a converter with good efficiency, these I.R drops are small compared to V_{OUT}, so do not greatly affect the current waveforms, but are exaggerated in FIG. **4** for the purposes of explanation.

[0103] As mentioned, if the load current demand decreases, for a constant V_{OUT} and V_{IN} the current waveforms shown in FIG. **4** will fall. The required valley current may fall to zero or may go negative as the current demand decreases. The inductor current going negative is inefficient as this means that the output capacitor is charging back into the converter (and to ground through the NMOS switch). In essence charge supplied to the output capacitor **C1** is therefore wasted.

[0104] One aspect of the present invention therefore provides a mode of operating a DC-DC converter in Valley Current Mode that prevents the inductor current from reversing, i.e. the current flow going negative and charging back to the DC-DC converter. This aspect of the present invention relates to control mechanisms for DC-DC converters that maintain a high efficiency.

[0105] In this mode of operation the low side supply switch, i.e. the NMOS, is turned off before the inductor current goes negative. The low side switch is therefore turned off before the high-side PMOS switch is turned on. In other words there is a divorce in the points in the inductor current cycle between the turn-off of the NMOS power switch, and the turn-on of the PMOS power switch, so there is a phase where neither conducts, and possibly even a phase of no inductor current.

[0106] Operation in a mode where the inductor current is maintained at zero for part of the duty cycle is known as Discontinuous Conduction Mode (DCM) or sometimes as Discontinuous Current Mode. DCM is a known mode of operation in Peak Mode Control DC-DC converters. This aspect of the present invention implements DCM in a Valley Current Mode control system. Operation of a DC-DC converter where there is no divorce in switching between the PMOS and NMOS is referred to a Continuous Conduction (or Current) Mode (CCM).

[0107] FIG. **5** shows a DC-DC converter according to an embodiment of the invention. The DC-DC converter comprises an output stage **202** coupled to an inductor L and output capacitor C1 as described above with relation to FIG. **2**. The DC-DC converter also has a level shifter **204** and voltage error block **205** as described above in relation to FIG. **2**. However the current loop block **501** of this embodiment comprises further elements Zero Cross Detect circuitry **850** and NDiodeDetect circuitry **750** connected to the drain of the NMOS **20**. Also the Ramp Generator **500** is modified to include an optional extra slope, and the Current Sensor Amp **800** has a Hold function. Duty modulator **900** is also modified to provide the additional mode of control. The operation of these blocks will be described below. Embodiments of current sense circuit **800**, ramp modulator **500** and duty modulator **900** are shown in FIGS. **12** to **14** respectively.

[0108] The operation of the circuit including inventive features will be described with respect to the operational waveforms shown in FIGS. **6** to **9**, starting with operation at high load currents, and progressing through different regimes of operation at progressively lower currents. It is assumed that V_{IN} and V_{OUT} are constant during this sequence.

[0109] As stated above, there is now a divorce in the points in the inductor current cycle between the turn off of the NMOS power switch, and the turn on of the PMOS power switch. Ideally, the NMOS should be turned off exactly when the current through it has decayed to zero. This could be detected by monitoring when the drain-source voltage across the NMOS has fallen to zero, for instance by using a comparator. However, inevitably there will be propagation delays in comparator responding and in driving through logic and pre-driver circuitry to actually control the NMOS to turn off. Also the comparator may have a random input offset voltage.

[0110] In this DC-DC converter therefore a signal derived from the source-drain voltage of the NMOS is compared, by Zero Cross Detect circuitry, to a threshold level corresponding to some pedestal current level Iped. The pedestal current level Iped is chosen such that, with worst case delays and offset, the NMOS switch **20** will be effectively switched off before the current through it changes polarity. When the pedestal current limit Iped is reached the Zero Cross Detect Circuitry **850** generates a signal, ILIM_ZC instructing the Duty Modulator to turn the low-side switch **20** off. The zero cross detection circuit **850** may therefore comprise a comparator arrangement as will be understood by one skilled in the art. The comparator arrangement may be a zero crossing comparator as described in which case the pedestal level Iped is achieved by choice of an appropriate offset. It would alternatively be possible to use a comparator with zero offset, or a different offset, and compare against an appropriate threshold level.

[0111] This Iped value may be fixed by design, or may be designed to automatically alter in synchronism with say the V_{SEL} signal (setting the desired output voltage) or a measured output voltage. The Iped value may be programmable to account for a specified inductor value. In general Iped may be programmable to account for variables that may alter current slew rates and thus the current headroom needed for a fixed delay time. The skilled person will be aware of how to generate a reference level equal to a desired Iped for use in the comparison circuit.

[0112] This deliberate offset in the comparator threshold introduces a zone of operation on the boundary between CCM and DCM where inductor current never quite decays to zero. Embodiments described herein allow current mode control to be maintained in such a zone of operation, and into full DCM which offers advantages in terms of seamless control, reduced transients and the ability to enter pulse skip mode of operation.

[0113] Transition between CCM and DCM

[0114] To illustrate operation in this region, FIG. **6** shows a selection of inductor currents and voltages at node LX for the same V_{IN} and V_{OUT}, as the average output current is reduced further. To account for offset voltages in the zero cross detector **850** and propagation delays before the output NMOS effectively switches, and ensure that the NMOS turns off before the inductor current reaches zero, i.e. before the NMOS drain voltage reaches zero, the current threshold level is set to a positive level, Iped, illustrated as threshold **1007** in FIG. **6**. Typically this would correspond to a drain voltage of the order of a few tens of mV. As mentioned above, because of the propagation delays, the power NMOS will usually shut off a short time later and thus at a current Ibreak (line **1008**) somewhat less than Iped. To a good approximation, the delays will not vary much with current, and the slope of the current waveform is a constant V_{OUT}/L, so the difference between Iped and Ibreak will be constant and hence break will also be constant (for inductor currents that are above Iped when the NMOS turns on—operation in the regime when the inductor current in below Iped when the NMOS turns on will be described later).

[0115] At the instant (I=Ibreak) when the NMOS effectively switches off, there will still be inductor current flowing towards the load. Since the NMOS is off, this current is forced to flow through the drain-bulk diode instead. The skilled person will appreciate that the NMOS transistor will have a parasitic drain bulk diode. FIG. **3** shows the output stage **202** of DC-DC converter with the parasitic diode **301** of the NMOS switch **20** shown as a separate parallel diode for the purposes of explanation. The PMOS switch **10** likewise has a similar parasitic diode **302**.

[0116] When the NMOS device **20** is turned on, its associated parasitic diode **301** is shunted to ground by this NMOS **20** and, so long as the current through the switch **20** is not sufficient to induce an I.R drop larger than a diode's on-voltage (say 0.5V) across the parasitic diode **301**, the diode **301** will not turn on. The diode **301** is however active if the NMOS device **20** turns off while there is still a current flowing from ground to the drain node: this will always be true if the current in the output filtering inductor L is flowing to the output.

[0117] When the inductor current reaches zero, the diode current will extinguish and the LX node will move from its negative voltage state, and will, if sufficient time is permitted, reach a steady-state output voltage substantially equal to that on the output voltage V_{OUT}. (In practice there will be some damped oscillations, not illustrated, at this transient due to stray capacitances and inductances on this node).

[0118] It should be noted that if there is a current in the opposite direction when the NMOS **20** is turned off, the node LX will fly high until it can find a sink for its current, possibly a similar body diode **302** inherent to a PMOS **10** providing the high-side drive of this output stage **202**.

[0119] Whilst an NMOS switch will have an inherent body diode associated with it, a separate diode (or other unidirectional current device) could be specifically provided in parallel with the low side switch **20** to control current flow when the low side switch is off. This separate diode could be arranged to allow forward current to flow if the low side switch is turned off (before the PMOS is turned on) but to prevent current reversal in the inductor. Thus the diode **301** shown in FIG. **3** could alternatively be a separate external diode. Any suitable diode, preferably such as a low drop diode or Schottky diode could be used. If required an external diode could be provided for the high side switch as well. The rest of the description will refer to a body diode or parasitic diode of an NMOS switch for clarity but it will be understood that other external diodes could be used instead.

[0120] Referring back to FIG. **6** conduction through the low side parasitic diode **301** causes a change in inductor slope from V_{OUT}/L to $(V_{OUT}+\Phi)/L$ where Φ is the diode voltage. (This diode voltage will vary somewhat as the current decays, but may be of the order of 0.5V at these low currents). As described above, the break point of the slope will be at a current Ibreak largely independent of load current demand in this regime, i.e. mode, of operation.

[0121] Curves **1003** show the inductor current and voltage at node LX for operation in this mode. It can be seen that these waveforms correspond to a lower average current demand than those of **1001** and **1002** discussed above with relation to FIG. **4**. During a first part of the cycle the NMOS **20** is switched on at a clock edge as described previously. During this time the node LX is near ground and the inductor current decreases with a slope of V_{OUT}/L. At a point during the cycle the inductor current drops to Iped which starts the process of turning the NMOS switch **20** off. Propagation delays and offset errors however mean that the switch **20** actually only turns off at point **1004** later when the inductor current has reached Ibreak. At this point the NMOS **20** is off but there is still current flowing in the inductor and so current now flows through the body diode **301** of the NMOS **20**. The voltage at node LX jumps to a diode voltage below ground and current flows in the inductor with the increased slope of $(V_{OUT}+\Phi)/L$.

[0122] It will be appreciated therefore that a switch such as the NMOS **20** and PMOS **10** has various different states of operation. In an on-state the channel of the NMOS **20** (or PMOS **10**) is conductive and current can flow in either direction through the switch **20** (or **10**). In an off-state the channel is not conductive. However, under certain conditions current may flow through a body diode associated with the switch. Such a body diode passes current in one direction only i.e. the body diode is a uni-directional automatic switch. Once the current flow through the body diode is extinguished there is no current flow through the switch element at all. As used in this specification the terms "on" and "off", when referring to switches, refer to whether the controlled region of the switch is conducting or not. Thus, turning the NMOS **20** off refers to turning its channel region off so that no current flows through the channel region.

[0123] Having turned the NMOS **20** off, the PMOS **10** still needs to be turned on at some point. The required switching point for the PMOS turn-on can be derived graphically from the plot of FIG. **6**. For a given peak current, the slope of the PMOS conduction region is $(V_{IN}-V_{OUT})/L$, that of the initial NMOS conduction region is V_{OUT}/L, until I=Ibreak, and then $(V_{OUT}+\Phi)/L$. The required switching point is then defined graphically. As can be seen from FIG. **6**, this switching point moves to the left, denoting a higher duty cycle—physically the PMOS has to switch on longer to compensate for the higher loss of current during the phase when both NMOS and PMOS are off.

[0124] As mentioned above the use of a deliberate offset, Iped, such that the NMOS switch turns off before the inductor current reaches zero introduces a zone of operation on the boundary between CCM and DCM where the inductor current never quite decays to zero before the PMOS is turned on. The boundary of this zone is illustrated by curves **1005** and **1006**. Curve **1005** represents the case where the inductor current reaches the Iped threshold but the propagation delays mean that the NMOS is turned off just as the PMOS is turned on. Curve **1006** represents the boundary where the NMOS is actually turned off and conduction through the parasitic unidirectional switch, i.e. body diode, **301** of the NMOS occurs but the inductor current only just reaches zero as the PMOS is turned on.

[0125] This mode of operation therefore represents a transitional mode between traditional CCM and DCM. This mode may therefore be referred to as a "discontinuous switching mode" as the step of switching the NMOS off is not performed as part of the same process of switching the PMOS on. The skilled person will of course appreciate that a DC-DC converter may be designed such that the NMOS always turn off before the PMOS turns on (or that the PMOS turns off before the NMOS turns on) to avoid a conduction path straight from V_{IN} to ground. However such staggered switching is performed as part of the same switching process. In this mode of operation the NMOS switch is turned off as part of a separate process to the PMOS turning on as will be described.

[0126] For a continuous transition between CCM and DCM, it is desirable that the PMOS turn-on still be defined by the Duty Modulator **900**, i.e. by a comparison of the sensed current signal ISNS with the voltage loop error signal V_{ERROR} and a ramp signal waveform, possibly with slope compensation included in the ramp signal. However, as evident from the voltage waveform, the inductor current can no longer be estimated from the NMOS drain-source voltage. The inductor current is now passing through the body diode, and the voltage jumps down to a diode voltage drop below ground.

[0127] On a normal, un-isolated n-well CMOS process, the anode of diode **301** shown in FIG. **3** will be the substrate into which all the devices are manufactured. It is thus impossible to isolate just this part of the substrate, for example to place a series resistor between the anode and ground to sense the diode current. Thus, any current passing through the diode **301** cannot be detected. An isolated process, either with extra process steps to build a junction-isolated pocket of p silicon under the NMOS, or a silicon-on-insulator technology, would allow a sense resistor between the anode of the diode and ground, probably also connected to the NMOS source to sense the total current. Were a separate external diode present a sense resistor could be connected to the external diode. However, as discussed above, a series resistance will cause undesirable ohmic power losses.

[0128] Rather than sense the current by monitoring the NMOS itself, a separate series sense resistor could be used. If attached to LX, this will require differential sensing that would have to recover from the large common-mode signal when the PMOS **10** is on. Again the I.R drop required to produce an adequate signal would also impair the converter efficiency. A sense resistor in series with the source terminal would be more convenient but would fail to gather at least some of the current from the drain diode, much of which would flow to substrate and guard rings rather than laterally to the source. If the converter included an external diode in parallel with the low side switch to allow unidirectional current flow after the low side switch is turned off a sense resistor could be used in a path common to both the low side switch and external diode but as mentioned above use of a sense resistor would still add an I.R drop.

[0129] The embodiment shown in FIG. **5** therefore employs a lossless approach to detecting the current flow in the inductor but still allows for current loop control when the NMOS is off and hence the current flow can not be directly detected. As shown in FIG. **5** the current sense amplifier monitors the source drain voltage of the low side supply switch **20** to derive a signal indicative of the current flow through the NMOS **20** when the NMOS **20** is on. An aspect of the circuit shown in FIG. **5** is that when the zero cross detect circuitry **850** detects that the current flow through the NMOS reaches the threshold level Iped, and the output signal ILIM_ZC becomes true, the current sensor amp, **800**, is placed into a hold mode (by the derived HOLD signal shown), whereby the ISNS output current prevailing at the time that the hold signal became true is held on the ISNS output. In other words a value for the current sense signal, indicative of the inductor current, at the time just before the NMOS turns off is held as the ISNS signal after the NMOS has turned off i.e. the inductor current is effectively sampled and stored just before the low-side switch **20** turned off.

[0130] The true inductor current is then emulated by adding a component to the held ISNS value with a slope of $-(V_{OUT}+\Phi)/L$, before this signal is used for comparison in the Duty Modulator **900**. Practically, it is more convenient to add this slope to the ramp signal slope to get the same effect and thus, in one embodiment, ramp generator **500** comprises circuitry for adding an additional slope. This slope represents the emulated change in inductor current when the NMOS **20** is off and the change in inductor current is due to conduction through the parasitic diode **301** of the NMOS **20**. As mentioned above this ramp signal may be added to the slope compensation signal (which itself may be applied to either the ISNS signal or V_{ERROR} signal) but alternatively a ramp could be applied to the ISNS current signal to produce an emulated current signal. The emulated ramp could alternatively be applied to the V_{ERROR} signal. The emulated change in inductor current could be emulated by two or more ramp signals which are applied to various different signals so as to produce a combined effect which represents the change in inductor current when the NMOS is off.

[0131] The embodiment shown in FIG. **5** comprises circuitry for emulating the change in inductor current during a period when the low side switch, i.e. NMOS **20**, has turned off but there may still be conduction due to the fact that the NMOS switch **20** is designed to turn off before the current reaches zero. As described above the change in inductor current may be emulated accurately taking into account the exact voltage drop across the inductor during the period when the NMOS is turned off, however a reasonable approximation to the change in the inductor current is sufficient for many converters. By emulating the change in inductor current is meant providing, by any means, a representation or replication of the change of the change in inductor current, whether exact or estimated or approximated, i.e. any means of imitating or mimicking the expected change in inductor current.

[0132] Various solutions for emulating the change in inductor current could be envisaged and could be applied in alternative embodiments. For example, in an alternative arrangement when signal ILIM_ZC goes true, indicating that the NMOS **20** is about to turn off, the Duty Modulator **900** may switch to use a different current signal which, for example, emulates not only the change in inductor current but also the absolute value of inductor current, based on a knowledge of Ibreak. However, holding a value of the current sense signal ISNS is convenient as it preserves the actual value of the signal and means that the same signals are used by the Duty Modulator **900** during the period when the NMOS **20** is on, i.e. conducting, and the period when the NMOS **20** is off, i.e. non-conducting. Also, as will be described later, at lower currents again the value of Ibreak may change depending on the starting current when the NMOS is turned on. Similarly adding a ramp signal to the slope compensation signal simply involves changing the slope of a ramp which is already applied.

[0133] As will be clear from the discussion above the change in inductor current during the period when the NMOS is off, but the NMOS body diode is passing current, has a slope equal to $-(V_{OUT}+\Phi)/L$. For simplicity, however the emulated change in inductor current may be approximated by $-V_{OUT}/L$ without greatly disturbing the loop accuracy or dynamics, any error being corrected for by the voltage feedback loop. And in cases where V_{OUT} is programmed, for example by a digital input signal V_{SEL}, this extra ramp rate may be digitally programmed by the V_{SEL} signals, rather than by monitoring the output voltage directly. This avoids loading the output, making the converter more efficient, and removing the need for an electrically and physically large on-chip resistor. Any slope which approximates the actual change in inductor current may be used for the ramp but the more accurate the ramp slope the better the overall performance.

[0134] If the load current demand decreases further, eventually the real valley current reaches zero, i.e. the current through the NMOS body diode has time to decay to zero before the PMOS is due to turn on. The converter is now operating in a full DCM mode.

[0135] DCM Operation

[0136] Operation in full DCM is illustrated in FIG. **7**. Waveform **1009** illustrates a current level where the NMOS turns off at point **1010** and the inductor current reduces to zero at point **1011** before the PMOS turns on a point **1012**.

[0137] As described above, once node LX is no longer driven by either the NMOS or the PMOS, and the diode conduction stops, this node presents a high impedance to the inductor L. Ideally the node LX would just step up to a voltage equal to V_{OUT}. In practice the effect of parasitic inductances and capacitances on this high impedance node will result in voltage oscillations that may take some time to dampen down, but this does not affect the operation of the circuit.

[0138] The extinguishing of the inductor current is detected by the NDIODE DETECT block, **750**, of FIG. **5**. This circuitry monitors the voltage seen at the LX node. When the diode current extinguishes, the LX voltage starts to rise from a diode voltage below ground. When a threshold, such as zero, is met, the NDIODE_OFF signal of FIG. **5** goes true, causing the extra slope to no longer be added to the slope compensation signal. NDiode Detect circuit **750** therefore comprises a relatively simple comparator circuit as would be well understood by one skilled in the art.

[0139] At the point at which the NDIODE_OFF signal goes true the inductor current is zero and the change in the inductor current is also zero. Therefore the slope of the additional ramp signal is no longer applied. In the embodiment shown in FIG. **5** the ramp generator slope therefore changes back to the slope due to the slope compensation ramp only. The current sense signal ISNS is still maintained at the constant value held since the NMOS was switched off. Although the inductor current is now zero the change in inductor current has been added to the slope compensation signal to effectively null out the contribution from the ISNS signal and hence the ISNS signal must be maintained. Again however there are many ways in which the emulation of change in inductor current could be achieved. In other arrangements, where the additional ramp signal is applied separately the value of the additional ramp signal should ideally exactly compensate for the value of the held ISNS at the point at which the NDIODE_OFF signal goes true. It would therefore be possible to discontinue both of these signals at the same time and simply drop to a value of zero on the ISNS signal. In practice however there may be a small offset between the value of the additional ramp signal and the held ISNS signal at the point at which NDIODE_OFF goes true. A small offset will not greatly affect the current loop control and so the values of both signals may be maintained to avoid a sudden jump to zero. This will avoid possible hunting or discontinuity of operation of the feedback loop around this loop operating point, and so assist the smoothness of the transition between operational regimes.

[0140] Whilst the NMOS body diode is conducting the rate of change of the inductor current is emulated and when the NMOS body diode stops conducting, indicating that the inductor current is zero, the emulated change is inductor current is also reduced to zero. It will be appreciated that the circuitry of this embodiment of the invention therefore effectively emulates the inductor current during the whole period that the NMOS switch is off but that for part of this period the emulated current remains substantially at zero. Therefore, both zero and non-zero current may be emulated. As mentioned, due to inaccuracies in the signals produced the effective emulated current may not be exactly zero. An effective emulated current of near zero is sufficient to allow the current control loop to function correctly. In general the emulation circuitry effectively emulates a changing inductor current in a first period, when the NMOS is off and current is flowing through the body diode, and a substantially static inductor current at or near zero in a second period when the inductor current has stopped and before the PMOS turns on.

[0141] The ramp including slope compensation still continues however, and eventually causes the Duty Modulator **900** to switch the PMOS **10** back on at the time required. This operation is described in more detail later with reference to FIG. **10***a*.

[0142] Also, as the current demand falls, the PMOS will be switched on later and later. (Note that in full DCM mode, such as illustrated in FIG. **7**, a drop in current demand leads to a reduction in duty cycle whereas in the transition phase between DCM and CCM, as illustrated in FIG. **6**, a drop in current demand actually leads to an increase in duty cycle). Thus, operating in DCM a drop in current demand may lead to a shorter duty cycle and a shorter period during which the PMOS is turned on.

[0143] However there is a minimum feasible pulse width for control of the PMOS switch and thus a minimum period in which the PMOS switch may be operational. This means that there is a minimum charge that may be passed by the PMOS each cycle. If current demand falls even further, then this minimum charge passed by the PMOS each cycle may be more than required by the load, so the output voltage would continue ramping up.

[0144] Pulse Skip Mode

[0145] In one embodiment a minimum conduction period T_{pmin} is defined for the PMOS, to give the PMOS time to turn on before reaching the clock edge where it must turn off. If the desired duty cycle reduces such that PMOS on time would be below this minimum conduction period the PMOS is prevented from turning on until the output voltage V_{OUT} has drooped enough to require recharging.

[0146] Thus, in this embodiment, a Pulse-Skip mode is enabled, not with an error voltage threshold or with an average current, but rather with this predetermined minimum power PMOS switch conduction period limit T_{pmin}.

[0147] A pulse skip mode of operation is thus advantageous in that it allows operation at low current demands. Pulse skip mode is also advantageous in that any switching losses associated with switching the power switches **10** and **20** are avoided whilst skipping pulses. This can avoid significant losses associated with operation of the converter herein illustrated and thus improve the efficiency of the converter at low current demands.

[0148] If the PMOS conduction period would be less than T_{pmin} in any particular DCM clock cycle, then the power PMOS switch conduction period is omitted in that particular cycle. While PMOS pulses are suppressed, the output voltage will sag, forcing the error voltage, V_{ERROR}, to rise eventually. The current, previously sampled by the current sensor block **800** at the last NMOS conduction period, is still held, the slope compensation is still active, and the loop will eventually recover normally by turning on the power PMOS switch **10** for a time greater than T_{pmin}. The PMOS switch will be turned on at a time defined as normal by the Duty Modulator based on the previously sampled current, the current slope compensation ramp, and the error voltage V_{ERROR}. This regime of operation is very much under voltage-mode control but this does not matter since it is guaranteed that the output current waveform is discontinuous, so the normal double-pole response from an inductor and capacitor filter so characteristic of voltage mode CCM, drops to a single pole response.

[0149] FIG. **7** shows a current waveform **1020** that would be suppressed by the pulse skipping.

[0150] It will be clear that in order to implement this embodiment one needs to determine the duration that the PMOS will be on for, prior to turning the PMOS on or not.

[0151] This duration, in VCM, corresponds to time between the current signal reaching the threshold level and the next clock edge turning the PMOS off, i.e. the start of the next cycle. The duration may be determined by monitoring the time between the last clock edge, i.e. start of the current cycle and the threshold being reached and determining the remaining cycle time based on a knowledge of the cycle frequency.

[0152] In a preferred embodiment however the system clock is delayed by an accurate delay. Thus the external clock signal **212** is delayed by a fixed delay, greater than or equal to the minimum PMOS conduction period, before being used to control the switching of the PMOS and NMOS. A signal derived from the undelayed clock signal can then be used to control timings. For example if the system clock is delayed by a period P and the minimum PMOS conduction period is T_{pmin} then, if the switch control signal is generated before a time T_1, where $T_1=P-T_{pmin}$, after the undelayed clock edge, the PMOS is switched on whereas as the switch control signal is generated after T_1 the pulse is skipped.

[0153] The apparatus may therefore comprise a delay means for delaying the clock edge used for switching by a known delay and a timer circuit which operates based on an undelayed (or less delayed) clock edge. The timer circuit may assert a no_switch signal a certain time after the undelayed clock edge until reset by the delayed clock edge. In this way the no_switch signal is asserted for the period of T_{pmin} before the delayed clock edge. Turn on of the PMOS is inhibited when the no_switch signal is asserted.

[0154] FIG. **16** illustrates one embodiment of a circuit arrangement that may be used to implement a pulse skip mode of operation. This circuit may form part of the Duty Modulator **900** shown in FIG. **5** or it may be a separate circuit for supplying signals to the Duty Modulator. A master clock signal CLK is received at an input **1601**. This signal is input to delay element **1602** to produce a delayed version of the clock signal. One delay element **1602** is shown in FIG. **16** but more than one delay element may be used. The delay element **1602** delays the master clock signal by a period t_d. The delayed signal CLK_SW is used as the master switching clock in the state machine of the Duty Modulator. A pulse generator (not shown) may be located before or after delay element **1602** to ensure that the delayed clock signal has a clock pulse with a desired pulse width, for example 20 ns or so. The master CLK signal is also received by a pulse generator **1603** which generates a pulse skip signal CLK_PS. Pulse skip signal CLK_PS goes high in response to the rising edge of the master clock pulse and remains high for a period at least equal to t_d. Preferably pulse skip signal CLK_PS has a pulse width greater than t_d so that it overlaps with the CLK_SW signal to avoid glitches. For example the CLK_PS signal may remain high for a period equal to t_d plus the duration of the pulse of the delayed clock signal.

[0155] The CLK_PS signal is received by another part of the Duty Modulator circuit which is arranged so that the PMOS switch can not be turned on whilst the CLK_PS signal is high. Thus, for a period of time before the start of the next cycle (as defined by the CLK_SW) signal the PMOS switch is inhibited from being turned on. The duration of this period, T_{pmin}, is effectively set by t_d and any propagation delays inherent in the logic. Ignoring propagation delays the period T_{pmin} is equal to the delay duration t_d. The delay duration may be set according to the frequency of operation of the converter.

[0156] It will be appreciated that other clock signals may be derived from the master clock, for instance a reset clock signal for resetting various logic blocks and/or one or more clock signals used to clock various logic block, flip-flops etc. However the only the signals directly relevant for pulse skip are shown for clarity.

[0157] As the current demand falls even further, the current through the NMOS will decay below the threshold Iped earlier and earlier. FIG. **8** shows waveforms for lower current levels, but with the time axis shifted half a period to focus on the region of interest. Also the relative slopes of the charging and discharging of the inductor have been changed, with a slower PMOS slope, representing a smaller V_{IN}-V_{OUT} relative to V_{OUT}, to illustrate a problem of operation.

[0158] As discussed previously there is a propagation delay T_{np} between when the sensed current passes the Iped threshold and when the NMOS actually turns off. So in the case of a current that is exactly Iped when the PMOS turns off and NMOS turns on, as illustrated by waveform **1013**, the NMOS will be kept on for a time T_{np} turning off at Ibreak. Also the sensed current is preset high before the PMOS/NMOS transition and the comparator of the Zero Crossing Detect circuit is reset, so even if the current at the PMOS/NMOS transition is less then Iped, as shown by waveform **1014**, the NMOS will still be kept on for a time T_{np}. So the sensed current when the NMOS turns off will decrease below the previous value of Ibreak, rather than stay constant. Thus the current decays initially at a slope V_{OUT}/L until time T_{np} and then, as the output node jumps to a diode voltage drop below ground, decays at $(V_{OUT}+\Phi)/L$ until decayed to zero.

[0159] The PMOS then turns on at the appropriate time before the next cycle starts to give a steady state peak current and hence the required average output current to the load. As above, the turn-on is still under control of the Duty Modulator **900**, with the sensed current sampled and held corresponding to Ibreak (with Ibreak now decreasing) and with the emulated slope added during the diode conduction period. If the current demand were to decrease further then the PMOS would turn on later, eventually getting into the pulse-skip mode as discussed above.

[0160] However, as shown in the solid curve **1016** in FIG. **8**, at very low average output currents, when the power NMOS switch **20**, is forced on for its minimum T_{npp}, the condition will eventually be reached when the inductor current is zero or negative by the end of the NMOS conduction period, i.e. the NMOS will start to sink current from the load. When the NMOS eventually turns off, the inductor will still require current in this direction, so node LX will fly high until being caught by the PMOS body diode **302**, which will then pass this current. The current will decay, at a rate $(V_{IN}+\Phi-V_{OUT})/L$, to zero, whereupon the driver output will become high impedance and the output will fall to V_{OUT}, albeit probably with some voltage oscillation in a real circuit. This voltage spike is undesirable per se, but more importantly this activity will waste power, first in unnecessary dissipation in the NMOS and the NMOS taking power away from the load, then in power loss in the PMOS body diode. In detail, on an n-well CMOS process, the PMOS "diode" will actually act as a vertical pnp transistor, with the drain as the emitter and V_{IN} as the base, and the substrate as collector, so that much of the diode current will flow to substrate through a voltage drop of VIN+Φ, which is much larger than just the diode drop Φ. Also there is the possibility that the NMOS channel current can cross zero early enough for the subsequent flow of charge from the load to actually be equal or greater than the charge supplied to the load earlier in the cycle, i.e. to actually fail to charge the load at all.

[0161] The outer loop would eventually compensate for these effects, but the reverse current through the NMOS would disadvantageously cause extra power losses.

[0162] Furthermore the loop might not be able to operate in a pulse-skipping mode in these conditions, so the power saving possible by pulse-skipping would not be realised. Under some conditions of V_{IN} and V_{OUT} as the current demand falls the condition described above, where the minimum NMOS conduction time would result in a negative current flow in the inductor, may occur before the duty cycle has reduced to less than the defined minimum PMOS conduction time T_{pmin}, i.e. before pulse skip mode has been entered. This power wastage may keep the current demand required sufficiently high that the duty cycle is always above the PMOS minimum conduction time. Thus pulse skipping mode would not be entered.

[0163] Diode Mode

[0164] To avoid this problem, in accordance with the present invention, the DC-DC converter is operable in a mode, which may be termed a "diode mode", where the high side switch may be turned on but, when it is turned off, the low side switch is not turned on and current flows through a parallel path. In one embodiment of the invention, after the PMOS switches off, the current is carried by the NMOS body diode (which will automatically shut off when it becomes reverse biased) rather than by the NMOS channel (which can conduct in both directions). In other words, rather than operate such that the NMOS is always turned on after the PMOS has been turned on, in diode mode the PMOS may be turned off and the NMOS maintained in an off state such that any current is conducted via the body diode only. As mentioned above an NMOS has an inherent body diode but, in another embodiment of the present invention, a separate external diode, or other unidirectional switch element, could be provided in parallel with the low side switch instead. In this diode mode the PMOS may be turned on when the (emulated) current signal crosses the V_{ERROR} threshold (as modified with a slope compensation ramp) in a first cycle and then again in a subsequent without the NMOS being turned on in between. This diode mode of operation may occur for several successive cycles.

[0165] In principle, the NMOS could be turned off as soon as the current crosses zero. But, due to the same propagation delay and offset issues described above, the NMOS would only actually turn off after a delay similar to T_{np}—which would be too late.

[0166] One embodiment of the invention therefore detects whether the current has reversed, i.e. crossed zero, during one cycle, and, if so, forces the NMOS off in the next cycle. In other words a negative current is detected in one cycle and such detection prevents a negative current situation from reoccurring in the next cycle. Following such detection, the NMOS may be inhibited from turning on at the next clock edge. However by then there has already been one cycle with undesired behaviour. Further, such an arrangement requires a detection of current flow in the NMOS. Thus the NMOS has to be on in one cycle so that the diode mode can be instigated for the subsequent cycle. In an extreme case this could lead to the undesired behaviour every other cycle.

[0167] In a preferred embodiment a minimum NMOS conduction time threshold, T_{nmin}, that is somewhat longer than t_{np}, is defined. If the current reaches zero before this extended time, then the control circuitry forces the NMOS not to turn on the next cycle. This is illustrated in FIG. **9**. Solid curve **1015** illustrates a waveform at a low current demand. The initial part of the curve shows the PMOS on phase where the inductor current increases. At the next clock edge the PMOS turns off and the NMOS turns on. The current in the NMOS is already less than Iped but the propagation delays mean that the NMOS does not turn off until the end of period T_{np}. At this point the inductor current is still positive and so diode conduction occurs until the inductor current reaches zero at point **1018**. The point at which the diode current reaches zero is less than the defined minimum conduction period, indicating that the current demand is close to the limit where the minimum NMOS on time, T_{np}, may lead to a negative current. Hence the converter enters diode mode and inhibits the NMOS from turning on in a subsequent cycle. In this subsequent cycle the PMOS may still turn on at the same time and hence the first part of curve **1015** would be repeated. However the NMOS would be prevented from turning on at the next clock edge.

Thus in this cycle, the drain-bulk diode of the power NMOS switch sources the current set up in the inductor by the PMOS. As described previously this slew rate will be higher, $(V_{OUT}+\Phi)/L$ rather than V_{OUT}/L, so the current will decay even earlier, as shown by curve **1017** which represents the current and voltage waveforms in diode mode.

[0168] The system remains in this mode until the current demand increases or the PMOS current recovers enough to drive the zero-cross point past T_{nmin} (illustrated by dashed curve **1019**) after which the previous mode of operation will resume. As mentioned, when operating in diode mode, the slope of current decrease is greater than in non-diode mode. It can be seen therefore that there is an inherent degree of hysteresis in entering and exiting diode mode in that the peak inductor current required to enter diode mode is lower than the peak inductor current to exit diode mode. It will, of course, be appreciated that once operating in diode mode, as the current decays more quickly than in non-diode mode operation, the converter may need to slightly increase the charge supplied during the PMOS conduction time to compensate.

[0169] By setting a conduction time threshold which is longer than the minimum propagation delay T_{np}, this embodiment of the present invention pre-empts the undesired behaviour. If the NMOS is on for a duration in one cycle which is less than a time threshold (i.e. the defined duration T_{nmin})—but which is greater than the minimum propagation time T_{np}—there will be no reverse current but the next cycle the NMOS will not turn on. The use of diode mode guarantees that pulse skip mode can be entered when appropriate.

[0170] It should be noted that in diode mode the turn on of the NMOS is inhibited in a subsequent cycle. The inhibition could be applied in the very next cycle. However, if in the next cycle the converter enters pulse skip mode there will be no current flow in the inductor at all in the next cycle. In such a case the diode mode preferably inhibits the NMOS from turning on after the next time that the PMOS has been on. In other words, if the inductor current reaches zero in a time period shorter than T_{nmin} in a time period, the NMOS is inhibited from turning on at the clock edge following the next time that the PMOS has been switched on. It is preferable to maintain diode mode until the PMOS has been on to prevent diode mode being missed. Alternatively, diode mode may only apply to the very next cycle but if the converter has been operating in a pulse skip mode it could be arranged such that the first cycle where a pulse in not skipped (following a skipped pulse) is operated in diode mode automatically. In other words it may be assumed a converter exiting pulse skip mode will need to be operated in diode mode.

[0171] FIG. **15** illustrates an embodiment of a circuit arrangement, which may for example be implemented within Duty Modulator **900**, for implementing diode mode. The circuit arrangement samples the NDIODE_OFF signal every cycle at a period effectively equal to T_{nmin} to determine whether or not the inductor current has reached zero. The NDIODE_OFF signal is input to a latch **1501** which latches when the NDIODE_OFF signal goes true, i.e. the output from the comparator indicates that the voltage at Node LX reaches zero. The latch **1501** rejects oscillations on node LX after the conduction of the NMOS body diode has ended. Although shown as part of the diode mode circuit the latch **1501** could be implemented within the NDIODE Detect circuitry. Latch **1501** is reset by a reset signal sent to the NDIODE detector comparator. The output of latch **1501** is provided to D type flip flop **1502** and sampled at an appropriate clock edge. The clock edge is derived from the NMOS ON signal, which is derived from feedback from the switch driver, passed through delays **1503** and **1504**. Two delays are shown in FIG. **15** for explanation purpose but a single delay or more than two delays may be used to provide the correct delay. Delay **1503** provides a delay which effectively provides a delay matched to the zero cross comparator and NMOS switch off time, i.e. the minimum conduction time of the NMOS. Delay **1504** provides a delay to allow for delays in the NDIODE detect comparator and logic in generating the NDIODE_OFF signal.

[0172] When the delayed clock edge is received by D type flip flop **1502** the state of the latched NDIODE_OFF signal is sampled. If the output is false, this means that inductor current has not yet reached zero and diode mode is not initiated. If the output is true this means that the inductor current reached zero in a time less than T_{nmin} and Diode Mode is enabled. The output of the flip flop **1502** therefore comprises a diode mode signal which is used by the Duty Modulator to determine whether or not to inhibit turn on off the NMOS at the start of the next cycle.

[0173] It will be appreciated that in Diode Mode the NMOS is not turned on and so the feedback from the NMOS switch driver can not be used. In this instance an appropriate signal is created. The PMOS ON signal is inverted by inverter **1506** and delayed by delay **1507** by a delay corresponding to the delay between switching the PMOS off and switching the NMOS on. The result is a signal that goes high at the time that the NMOS would have turned on were the circuit not in Diode Mode. This signal is selected by multiplexer **1505** responsive to the Diode Mode Signal output.

[0174] It should be noted that diode mode has been described in relation to Valley Current Mode control of a DC-DC converter. However the principle of diode mode is equally applicable to a Peak Current Mode controller. In Peak Mode Control, the PMOS is turned on at a clock edge and is turned off when the current reaches the threshold. At this point the PMOS is turned off and the NMOS is turned on. To prevent power wastage, as described above, it may be preferred to switch the NMOS switch off before the current goes negative. However, as described above there will again be propagation delays and offsets associated with any comparison circuitry and hence there will be a minimum effective NMOS on time. Thus the minimum period T_{nmin} may be defined as described above and if, in any cycle, the NMOS current reaches zero in a duration less than T_{nmin} the NMOS may be inhibited from turning on in a subsequent period.

[0175] The operation of the embodiments of the present invention is now described including more detail of the Current Loop block and waveforms therein rather than focussing on the output waveforms.

[0176] FIG. **10***a* shows the control signals in detail when the DC-DC converter is operating in full DCM mode, as described above with relation to FIG. **7**.

[0177] The first trace shows the inductor current, similar to the current curve shown in FIG. **7**, with a first phase, to time t**1**, of decay with a slope of V_{OUT}/L when the NMOS is ON, a steeper slope of $(V_{OUT}+\Phi)/L$ as it passes through the NMOS body diode until the current decays to zero at t**2**, a third phase of zero current, until t**3**, when the PMOS is turned on.

[0178] The second trace shows the sensed current, processed by the block **800**. Initially this follows the droop of the inductor current, until it drops to Ibreak, where it is held constant. Once the PMOS turns on, the sensed current output is set to a higher value to ensure that it is well above the Iped threshold during any transient when it is enabled as the PMOS turns off and the NMOS turns on.

[0179] The third trace shows the current due to slope compensation plus additional ramp. This starts of with a slope equivalent to $(V_{IN}-V_{OUT})/L$ but increases in slope by nominally $(V_{OUT}+\Phi)/L$ between t**1** and t**2** to emulate the increase in slope of the actual inductor current. This extra slope is removed after the current goes to zero at t**2**.

[0180] The fourth trace shows the voltage at an internal summing node, where the ISNS and the slope compensation current are summed. The PMOS turns on when this crosses V_{ERROR}. Note the voltage loop will slowly settle to an appropriate V_{ERROR} value to generate the correct voltage after any change in load current demand.

[0181] The remaining traces are the control signals. PWM is an internal node pulsed high after the summing node voltage crosses V_{ERROR}, and reset by the edge of external clock CLK. ILIM_ZC gives a triggering pulse when the NMOS current crosses the pedestal threshold Iped, as determined by Zero cross detect circuit **850**. This sets the EMULATE signal which is the signal to add the additional ramp to the generated slope compensation to emulate the change in inductor current. EMULATE is reset by the NDIODE_OFF signal generated by the NDiode detect block **750** which senses the output voltage passing from negative to positive when the body diode stops conducting. The NDIODE_OFF signal is itself reset when the PMOS is turned on. HOLD is a combination of EMULATE and NDIODE_OFF and is used to cause the current sensor block **800** to hold the sensed current value. NGATE and PGATE are the drive signals for the NMOS and PMOS gates.

[0182] FIG. **10***b* shows operation in the transition phase between CCM and DCM operation, in conditions similar to those of the dotted curve in FIG. **6**, where the actual valley current is above zero but below Iped and Ibreak. The same signal traces are shown as in FIG. **10***a*.

[0183] The control scheme has to incorporate the current control loop in this region since the inductor current has not decayed to zero and the overall loop would be intrinsically second-order in nature without some current information to compensate it.

[0184] Unfortunately, the current sensor, **800**, cannot supply any current information if the power NMOS switch **20** is off. Instead, the current information is emulated by sampling the current prevailing in the sensor during the time when the switch is turned off, and is supplemented by the additional emulated current ramp while the drain-bulk diode **301** is conducting.

[0185] Operation is similar to the true DCM above except that the actual inductor current never decays to zero, so NDIODE_OFF is never triggered, and so the extra slope compensation ramp is still applied when the summing node voltage passes V_{ERROR}. Also the net effect of this emulation is that the overall inductor current ramp plus slope compensation ramp—to first order—is identical to that prevailing in CCM where the average inductor current is high enough so that the zero cross detection circuit never trips. The transitions between full CCM, CCM under NMOS diode conduction, and DCM are therefore smooth.

[0186] The embodiments of the present invention therefore provide a DC-DC converter operable in valley current mode and operable in a number of different modes. The use of the different modes allows the DC-DC converter to maintain accurate current mode control in CCM, and through a transitional phase to full DCM. In the transitional phase, although the NMOS is turned off the current loop is still active and current loop control is provided by emulating the change in inductor current. This embodiment of the present invention therefore provides seamless transfer between CCM and DCM and vice versa. The control mechanism uses a lossless current sensing approach and thus losses associated with a series sense resistor are avoided. The DC-DC converter may operate a fixed frequency in CCM, the transitional phase and DCM—although variable frequency operation may be implemented if desired. A pulse skip mode is also available which allows for significant efficiency gains at low current demands by preventing switching when unnecessary and thus reducing the relatively switching losses. A diode mode of operation may be used at low current demands to guarantee that pulse skip mode will be entered. These modes of operation are automatic in operation (if enabled). The onset of the transitional phase is set by the value of Iped and the converter will automatically operate in CCM, transitional phase or DCM depending on the load current. If the minimum conduction time periods are enabled the converter will also automatically enter pulse skip and/or diode mode as appropriate and the transition between modes will be automatic and continuous, i.e. the control method is the same between all modes and there is no change from one set of control signals to another. The control loop is maintained in each of CCM, the transitional phase, DCM and pulse skip, even though no current information may be available.

[0187] The skilled person will appreciate that CCM mode control offers the most stable control method but the other modes of operation offer efficiency savings. FIG. **11** illustrates the relative efficiency of a DC-DC converter operating purely in CCM, a forced CCM mode (FCCM), with a converter that automatically operates switches to DCM, via the transitional phase, and then to pulse skip mode at increasing low current demands. The curves show efficiency against current on a logarithmic scale. The curves shown in FIG. **11** apply to identical converters where only the mode of operation is changed and assume a constant V_{IN} and a constant V_{OUT} throughout the operating range.

[0188] The lower curve **1101** shows the efficiency of the converter operating in FCCM. At relatively high current loads, around 200-300 mA, the converter is very efficient. However as the load current falls the efficiency drops markedly, due partly to the fact that the NMOS will pass negative current for a part of each cycle.

[0189] The upper curve **1102** shows operation of a converter with automatic mode switching enabled. At currents of 200 mA or above the converter is operating in CCM mode and hence the efficiency is effectively the same as for a converter operating in FCCM. Below 200 mA the transitional phase through to DCM proper is starting and the curves start to deviate with the converter operating in DCM being more efficient. Below about 20 mA in this example pulse skipping starts and there is a jump in efficiency as the switching losses are avoided. At lower currents still it can be seen that the converter operating in pulse skip mode is significantly more efficient than a corresponding converter operating in FCCM.

[0190] These significant efficiency saving can have a large impact on battery life for portable electronic device applications. However in some applications the efficiency gains may not be as much of a concern and it may be preferred to operate in FCCM to provide the best control over voltage ripple and the like. Conveniently therefore a mode control signal input to the duty controller, for example mode control signal **106** shown in FIG. **1**, may determine whether the converter operates in FCCM or whether DCM and pulse skip modes of operation are enabled.

[0191] Various aspect and embodiments of the circuitry for implementing the modes described above will now be described.

[0192] FIG. **12** illustrates one embodiment of a current sensor that has a Hold capability.

[0193] The N-channel current sensor **800** interface to the power switch **20** is shown.

[0194] A reference voltage V_A is generated on the non-inverting input node of amplifier **805**. V_A is proportional to the current **801** and the series combination of the resistances of NMOS devices **803** and **804**. This bias voltage V_A is replicated at the inverting input node of amplifier **805** by the action of feedback, ensuring that node B, the drain of device **810**, is held at V_A.

[0195] In normal operation, switch **809** is closed and switches **807** and **808** are open, allowing a current path through devices **20**, **809**, **811**, **810**, **812**, and **813**. Since node B is held at a constant voltage the current through **809**, **811**, **810** is given by $(V_A-V(LX))/R_{SX}$ where R_{SX} is R**809**+R**811**+R**810**, i.e. the sum of the resistances of these three devices. Thus as the inductor current varies, the current through the NMOS also varies (the current through R**809** is small compared to that through NMOS **20** and inductor L), so the voltage on LX varies due to the varying I.R drop across NMOS **20**. This variation modulates the voltage across Rsx. Since Rsx is also a MOS channel resistance which will to first order track proportionately that of NMOS **20**, the net result is a modulation in current through Rsx through **812** to the output that is independent of MOS channel resistance and is a pure ratioed copy of the current through NMOS **20**, with ratio dependent mainly on the respective aspect ratios of the transistors involved.

[0196] Normally the current in the inductor is towards the load, as shown. This pulls the NMOS drain node LX below ground and increases the current through **809**. However in some modes or during transients, the current may be of opposite polarity. Ignoring current source **802**, the maximum reverse current detectable would be that causing LX to rise to a voltage V_A, i.e. V_A/R**20** since **812** can only source, and not sink, current. Including current source **802** reduces this maximum reverse current.

[0197] When the current sensor is in track mode, i.e. when the NMOS is on and the actual current through the NMOS is being monitored, switch **815** is closed, and the current seen at node ISNS is created by the current mirror comprising devices **813**, **814**, and **815**. When in Hold mode, as determined by the HOLD control signal (which is inverted for control of switch **815**), the gate of mirror device **814** is open-circuited, and the gate stays at constant voltage, and hence its output current remains at the same value until reconnected. Known techniques, such as half-size devices clocked in anti-phase for example, are used to cancel the charge injection onto this gate node that would be caused by this switch turning off. Extra capacitance between gate and supply may be added, though proved to be unnecessary in this design as a gradual droop over time has little effect on the regulator output.

[0198] To obtain an accurate scaling value for ISNS versus absolute externally applied current, the current mirror **813**, **814**, and **815** may be made a digitally programmable current mirror composed of multiple elements to give a programmable current transfer ratio by standard techniques. In manufacture, a predetermined external current may be applied and the voltage developed across an internal on-chip resistor may be monitored and the current transfer ratio modified until a predetermined target voltage is developed across the on-chip resistor. This then fixes the regulator's "sense resistance" (strictly a transresistance) R_{SENSE} to a known value relative to other on-chip resistances, enabling a tight tolerance of the loop transfer function. There will still be some variation due to other on-chip resistances/capacitances over temperature, but manufacturing variations in the short channel NMOS transistor resistance and offsets and current ratio errors in the Sensor Amp can be compensated.

[0199] The currents of devices **801** and **802** are inversely proportional to on-chip resistances similar to those used in the duty modulator block. Devices **803**, **804**, **810**, **811**, and switches **807**, **808**, and **809** are all scaled analogues of the resistance of the master power switch **20** in that they track each other over process, voltage supply, and temperature. That is the devices and switches are formed in the same area of the silicon so that any process variations affect all devices equally and the devices experience the same temperature and supply variations.

[0200] At the start of a period of duty cycle control, the current output of this current sensor should be reset to a value higher than that seen under normal conditions in order to prevent false triggering by the duty modulator block **900** of FIG. **5**. This reset path is achieved by closing switch **807** while keeping switches **808** and **809** open. This decouples the sensor from the power device **20** and, by virtue of the series combination of devices **810** and **807** being less than the series combination of devices **810**, **811**, and **809**, pushes the output current much higher than usual.

[0201] In order to save power, during some phases in DCM and pulse-skip modes, the path comprising devices **808**, **810**, **811**, **812**, and **813** is engaged which sets the ISNS output to the pedestal value seen during normal operation, rather than the higher reset value. This is achieved because the resistances of devices **808** and **809** are equal.

[0202] During CCM, switch **815** is closed. When the DC-DC converter is placed into the transitional mode between CCM and DCM, once zero current has been detected—actually always above zero, i.e. at Iped, to allow for offsets and propagation delays in the drive train—switch **815** is opened and the current produced on the ISNS output is held constant by the gate capacitance of device **814** at a level similar to that flowing just before the switch was opened.

[0203] FIG. **13** illustrates one embodiment of a ramp generator **500** which is capable of producing a slope compensation signal which may include a component emulating the change in inductor current.

[0204] It is apparent that the output current of the block is given by:

$$Iout(t) \equiv I_{512} + \frac{I_{507}}{M} - \frac{R_{504}}{R_{505} * M} * I_{506} - \frac{I_{506} + I_{503}}{M * C_{502} * R_{505}} * t$$

[0205] If the currents I_{503}, I_{506}, I_{507}, and I_{512} are ratiometric with an external current reference, the added voltage contribution seen at the output node due to the ramp generator block is a fixed voltage offset that is dependant on the manufacturing tolerance of the on-chip resistors, plus a time dependent ramp voltage independent of manufacturing tolerance in the on-chip resistors. The voltage offset may be reduced to zero to avoid dependence on on-chip resistance and to set the ramp to zero at the start of each cycle by judicious scaling of R_{504}, R_{505}, and M. The current source **503** may be controlled to change the slope of ramp to include the emulated change in inductor current when the NMOS is off and the body diode is conducting.

[0206] FIG. **14** shows a greatly simplified depiction of the duty modulator block with relevant connections as used in FIG. **5**

[0207] It consists of a bandgap voltage generator and internal resistor derived current source, **601**, a voltage comparator, **602**, two resistors, **603** and **604**, and a mode control block, **605**.

[0208] Mode control block comprises logic for generating a HOLD signal when signal ILIM_ZC goes true and keeping the hold signal high until reset—when the summing node voltage reaches V_{ERROR} as described above with reference to FIGS. **10***a* and **10***b*. It also comprises logic for generating an EMULATE signal when ILIM_ZC goes true until NDIODE_OFF goes true.

[0209] Mode control block may also receive an external mode control signal for switching between FCCM mode or automatic DCM and pulse skipping. When operating in FCCM the signal ILIM_ZC may simply be kept continually false and the converter will only switch the NMOS off when the signal on the summing node reaches V_{ERROR}. It may be preferable however to effectively deactivate NDiode detect block **750** and zero cross detect block **850** when operating in FCCM.

[0210] Whilst the above embodiments have been described in relation to a DC-DC buck converter the embodiments of the invention can be applied generally to switching regulators. The switching regulator may be part of a power management apparatus such as a power management integrated circuit (i.e. a PMIC). The embodiments of the invention may be useful for power management of any sub-systems of any form of electrical device, whether having a single power source or multiple power sources and whether portable or not. The embodiments of the present invention are particularly applicable to portable devices however such as: mobile computing devices such as laptops, netbooks, PDAs and the like; mobile communication devices such as radio telephones, cellular telephone, mobile email devices and the like; personal media players such as MP3 or other audio players, personal radios, video players; portable video game consoles and devices; personal navigation devices such as satellite navigators and GPS receivers, whether in-vehicle or hand-held or any other portable or battery operated device.

[0211] It should be noted that the above-mentioned embodiments illustrate rather than limit the invention, and that those skilled in the art will be able to design many alternative embodiments without departing from the scope of the appended claims. The word "comprising" does not exclude the presence of elements or steps other than those listed in a claim, "a" or "an" does not exclude a plurality, and a single processor or other unit may fulfil the functions of several units recited in the claims. Any reference signs in the claims shall not be construed so as to limit their scope.

1. A DC-DC converter comprising:

an inductor operably connected between a first node and an output node;

a high side switch operably connected between a high side supply input node and the first node;

a low side switch operably connected between a low side supply input node and the first node;

switch control circuitry for controlling said switches, wherein the switch control circuitry comprises first monitoring circuitry for determining whether a first time period between the high side switch turning off and the inductor current reaching zero is less than a threshold time period,

wherein if the first time period in one duty cycle is less than the threshold time period the switch control circuitry inhibits the low side switch from turning on in a subsequent cycle.

2. A DC-DC converter as claimed in claim **1** wherein if the first time period in one duty cycle is less than the threshold time period the switch control circuitry inhibits the low side switch from turning on following the next time that the high side switch has been on.

3. A DC-DC converter as claimed in claim **1** wherein the switch control circuitry is operable, in a cycle where turn on of the low side switch is not inhibited, to turn the low side switch off before the high side switch is turned on.

4. A DC-DC converter as claimed in claim **3** wherein the switch control circuitry comprises second monitoring circuitry for determining the current flow in the inductor from the electrical properties of the low side switch when the low side switch is on and monitoring current flow in the inductor against a current threshold and wherein the switch control circuitry is arranged to turn the low side switch off when the current threshold is reached.

5. A DC-DC converter as claimed in claim **4** wherein said current threshold is set such that the low side switch is turned off before the current flow through in the inductor reverses direction.

6. A DC-DC converter as claimed in claim **4** wherein the current threshold level is varied in response to a variation of a target output voltage.

7. A DC-DC converter as claimed in claim **1** wherein the first monitoring circuitry comprises a voltage threshold monitoring circuit for comparing the voltage of the first node with a threshold voltage when the low side switch is turned off.

8. A DC-DC converter as claimed in claim **7** wherein the threshold voltage is zero volts.

9. A DC-DC converter as claimed in claim **1** wherein the first monitoring circuitry comprises a first timer circuit configured to determine whether the inductor current has reached zero at a time equal to the time threshold period after the high side switch turns off.

10. A DC-DC converter as claimed in claim **9** wherein the first timer circuit is arranged to receive a control signal synchronous with a high side switch control signal and wherein the first timer circuit comprises at least one delay element for delaying said control signal by a delay equal to the threshold time period.

11. A DC-DC converter as claimed in claim **1** wherein the time threshold period is configurable.

12. A DC-DC converter as claimed in claim **1** wherein the low side switch is an NMOS transistor.

13. A DC-DC converter as claimed in claim **1** wherein the DC-DC converter is operable in valley mode control.

14. A DC-DC converter as claimed in claim **13** wherein the converter comprises circuitry for keeping a current feedback loop active when the low side switch is off.

15. A DC-DC as claimed in claim **14** wherein the circuitry for keeping a current feedback loop active when the low side switch is off comprises emulation circuitry for emulating the change in inductor current when the low side switch is off

16. A DC-DC converter as claimed in claim **13** wherein the switch control circuitry comprises current sense circuitry for determining the current flow in the inductor from the electrical properties of the low side switch when the low side switch is on.

17. A DC-DC converter as claimed in claim **1** wherein the DC-DC converter is operable in peak mode control.

18. A DC-DC converter as claimed in claim **1** wherein the switch control circuitry is operable in a pulse skip mode to prevent turning the high side switch on in a cycle.

19. A DC-DC converter as claimed in claim **18**, operable in valley mode control, wherein the switch control circuitry prevents turning the high side switch on in a cycle if a second time period between turning the high side switch on and turning the high side switch off would be less than a second threshold time period.

20. A DC-DC converter as claimed in claim **19** wherein the switch control circuitry comprises a second timer circuit for producing an inhibit signal which inhibits turn on of the high side switch, for a time period substantially equal to the second time threshold period, before a clock edge which would cause the high side switch to turn off.

21. A DC-DC converter as claimed in claim **20** wherein the second timer circuit comprises an input for receiving an input clock signal, a delay for producing a delayed clock signal and circuitry for generating the inhibit signal based on the input clock signal.

22. A DC-DC converter as claimed in claim **1** wherein the cycle frequency of the converter is constant.

23. A DC-DC converter as claimed in claim **1** comprising a diode in parallel with the low side switch to allow forward current to flow if the low side switch is turned off before the high side switch is turned on but to prevent current reversal in the inductor.

24. A method of controlling a DC-DC converter comprising an inductor operably connected between a first node and an output node; a high side switch operably connected between a high side supply input node and the first node; and a low side switch operably connected between a low side supply input node and the first node; the method comprising:

monitoring whether a first time period between the high side switch turning off and the inductor current reaching zero is less than a threshold time period, and

where the first time period in one duty cycle is less than the threshold time period the switch control circuitry inhibiting the low side switch from turning on in a subsequent cycle.

25. (canceled)

26. A DC-DC converter comprising:

an inductor operably connected between a first node and an output node;

a high side switch operably connected between a high side supply input node and the first node;

a low side switch operably connected between a low side supply input node and the first node;

switch control circuitry arranged to monitor the time between the high side switch turning off and the voltage at the first node reaching zero and, if said monitored time is less than a first time threshold, preventing the low side switch from subsequently turning on the next time the high side switch is turned on.

27. A DC-DC converter comprising:

an inductor operably connected between a first node and an output node;

a high side switch operably connected between a high side supply input node and the first node;

a low side switch operably connected between a low side supply input node and the first node; and

switch control circuitry operable in a first mode where the low side switch is not turned on following the high side switch being turned off.

28. A DC-DC converter operable in a mode wherein a low side switch is not turned on following activation and deactivation of a high side supply switch.

29. A power management integrated circuit comprising a DC-DC converter as claimed in claim **1**.

30. An electronic device comprising a DC-DC converter as claimed in claim **1**.

31. An electronic device as claimed in claim **30** wherein the device is one of: a portable computing device; a laptop computer; a personal data assistant; a personal media player; an mp3 player; a portable television; a mobile communications device; a mobile telephone; a navigation aid; a GPS device; a game console.

(57) **ABSTRACT**

Disclosed is an apparatus for harvesting leakage energy. The apparatus for harvesting leakage energy includes: an energy harvesting unit configured to harvest energy leaked while energy radiated from a transmitting unit of an energy transmitting apparatus is transmitted to a receiving unit of an energy receiving apparatus; and a harvesting circuit module configured to supply energy harvested by the energy harvesting unit to a load. In accordance with the embodiment of the present invention, energy efficiency of overall system can be increased by harvesting the leakage energy without affecting performance of a wireless power transmission system.

CROSS-REFERENCES TO RELATED APPLICATIONS

[0001] The present application claims priority under 35 U.S.C 119(a) to Korean Application No. 10-2012-0019957, filed on Feb. 27, 2012, in the Korean Intellectual Property Office, which is incorporated herein by reference in its entirety set forth in full.

BACKGROUND

[0002] Exemplary embodiments of the present invention relate to an apparatus for harvesting leakage energy, and more particularly, to an apparatus for harvesting leakage energy in a wireless power transmission system using a magnetic resonance or electromagnetic induction phenomenon.

[0003] Generally, devices driven using electricity as an energy source are supplied with power through a power line. However, there are problems in that a use of the power line hinders mobility of the devices or has a limitation in a position.

[0004] Recently, with a rapid use of a mobile device in addition to smart phones, a demand for wireless charging technologies has been increased. Therefore, research into a wireless power transmission system capable of transferring power wirelessly has been actively conducted.

[0005] Technologies of transmitting power wirelessly convert electric energy into an electromagnetic wave or a light wave that can be transmitted wirelessly and transmit power using electric field, magnetic field, or electromagnetic field and may be largely classified into an electromagnetic induction type, a magnetic resonance type, a microwave type, and the like.

[0006] The electromagnetic induction type is a type of generating induction current at two coils and transmitting energy, the magnetic resonance type is a type of using an evanescent wave coupling phenomenon of moving an electromagnetic wave from one medium to another medium through near field when two media are resonated at the same frequency, and the microwave type is a type of transmitting energy by radiating a microwave signal to the air through an antenna.

[0007] A physical quantity leaked while the physical quantity radiated from a resonator or a radiator is transmitted to a receiver by passing through a space is essentially present in the wireless power transmission system.

[0008] The energy leaked to the space acts as loss in the wireless power transmission system, thereby degrading overall transmission efficiency and energy efficiency.

[0009] As the related art, KR Patent Laid-Open No. 2011-0117732 (Oct. 27, 2011: Wireless Energy Transmission)

[0010] The above-mentioned technical configuration is a background art for helping understanding of the present invention and does not mean related arts well known in a technical field to which the present invention pertains.

SUMMARY

[0011] An embodiment of the present invention is directed to an apparatus for harvesting leakage energy capable of increasing energy efficiency by harvesting leakage energy without affecting a wireless power transmission system.

[0012] An embodiment of the present invention relates to an apparatus for harvesting leakage energy, including: an energy harvesting unit configured to harvest energy leaked while energy radiated from a transmitting unit of an energy transmitting apparatus is transmitted to a receiving unit of an energy receiving apparatus; and a harvesting circuit module configured to supply energy harvested by the energy harvesting unit to a load.

[0013] The energy harvesting unit may include: an inner loop coil configured to be disposed at an outer side of the transmitting unit or the receiving unit and having an opened side; and an outer loop coil configured to be disposed at an outer side of the inner loop coil and having an opened side, wherein the opened sides of the inner loop coil and the outer loop coil are connected to each other to form a single closed loop.

[0014] The energy harvesting unit may be disposed at the transmitting unit.

[0015] The energy harvesting unit may be disposed at a predetermined distance from the transmitting unit or the receiving unit.

[0016] The transmitting unit and the receiving unit may each be a transmitting coil and a receiving coil.

BRIEF DESCRIPTION OF THE DRAWINGS

[0017] The above and other aspects, features and other advantages will be more clearly understood from the following detailed description taken in conjunction with the accompanying drawings, in which:

[0018] FIG. **1** is a block diagram of a wireless power transmission system including an apparatus for harvesting leakage energy in accordance with an embodiment of the present invention;

[0019] FIG. **2** is a side view for describing an apparatus for harvesting leakage energy in accordance with an embodiment of the present invention;

[0020] FIG. **3** is a perspective view for describing an apparatus for harvesting leakage energy in accordance with an embodiment of the present invention;

[0021] FIG. **4** is a front view for describing an apparatus for harvesting leakage energy in accordance with an embodiment of the present invention;

[0022] FIG. **5** is a diagram for describing an energy harvesting principle of an apparatus for harvesting leakage energy in accordance with an embodiment of the present invention;

[0023] FIGS. **6**A and **6**B are diagrams for describing an effect of an apparatus for harvesting leakage energy in accordance with an embodiment of the present invention;

[0024] FIG. **7** is a graph for describing a change in a resonance frequency of a wireless power transmission system when using an apparatus for harvesting leakage energy in accordance with an embodiment of the present invention;

[0025] FIG. **8** is a graph for describing a change in a return loss of a wireless power transmission system when using an apparatus for harvesting leakage energy in accordance with an embodiment of the present invention;

[0026] FIG. **9** is a graph for describing a change in an insertion loss of a wireless power transmission system when using an apparatus for harvesting leakage energy in accordance with an embodiment of the present invention;

[0027] FIG. **10** is a graph for describing a change in loss according to a coupling coefficient between an energy transmitting unit and an energy harvesting unit in a wireless power transmission system when using an apparatus for harvesting leakage energy in accordance with an embodiment of the present invention.

DESCRIPTION OF SPECIFIC EMBODIMENTS

[0028] Hereinafter, an apparatus for harvesting leakage energy in accordance with embodiments of the present invention will be described with reference to the accompanying drawings. During the process, a thickness of lines, a size of components, or the like, illustrated in the drawings may be exaggeratedly illustrated for clearness and convenience of explanation. Further, the following terminologies are defined in consideration of the functions in the present invention and may be construed in different ways by intention or practice of users and operators. Therefore, the definitions of terms used in the present description should be construed based on the contents throughout the specification.

[0029] FIG. **1** is a block diagram of a wireless power transmission system including an apparatus for harvesting leakage energy in accordance with an embodiment of the present invention and FIG. **2** is a side view for describing an apparatus for harvesting leakage energy in accordance with an embodiment of the present invention.

[0030] In addition, FIG. **3** is a perspective view for describing an apparatus for harvesting leakage energy in accordance with an embodiment of the present invention and FIG. **4** is a front view for describing an apparatus for harvesting leakage energy in accordance with an embodiment of the present invention.

[0031] As illustrated in FIG. **1**, a wireless power transmission system in accordance with an embodiment of the present invention includes an energy transmitting apparatus **10**, an energy receiving apparatus **20**, and an apparatus for harvesting leakage energy **30**.

[0032] The energy transmitting unit **10** includes a transmitting circuit module **13** generates an RF signal to be transmitted and amplifies and outputs the generated RF signal and a transmitting unit **11** that receives the RF signal from the transmitting circuit module **13** to radiate energy to the energy receiving apparatus **20**.

[0033] The energy receiving apparatus **20** includes a receiving unit **21** that receives energy radiated from the transmitting unit **11** and transmits the received energy to a receiving circuit module **23** and the receiving circuit module **23** that receives energy from the receiver **21** and supplies the received energy to a load.

[0034] In this configuration, the transmitting unit **11** and the receiving unit **21** may be a transmitting coil **110** and a receiving coil **210** that may each transmit or receive energy by electromagnetic induction and a resonator (not illustrated) that may transmit or receive energy using a magnetic resonance type.

[0035] Meanwhile, as illustrated in FIG. **1**, the apparatus for harvesting leakage energy **30** in accordance with the embodiment of the present invention harvest energy leaked during the transmission of the energy radiated from the energy transmitting apparatus **10** to the energy receiving apparatus **20** and includes an energy harvesting unit **31** and a harvesting circuit module **33**.

[0036] The energy harvesting unit **31** may be disposed at a predetermined distance from an outer side of the transmitting unit **11** to harvest energy leaked from the transmitting unit **11**.

[0037] In this case, the energy harvesting unit **31** may be disposed at a predetermined distance from an outer side of the receiving unit **31** rather than the transmitting unit **11** to harvest energy leaked from the receiving unit **21** and may be disposed at various positions but may be preferably disposed at the transmitting unit **11** side to which energy is radiated in terms of the energy harvesting efficiency.

[0038] As illustrated in FIGS. **2** and **3**, the energy harvesting unit **31** may be a harvesting coil **310** in a loop form that harvests the energy leaked from the transmitting coil **110** or the receiving coil **210** and as illustrated in FIG. **4**, the harvesting coil **310** may be configured to include an inner loop coil **311** and an outer loop coil **312**.

[0039] In this configuration, the harvesting coil **310** including the inner loop coil **311** and the outer loop coil **312** may be configured of a conductor in which current may flow.

[0040] Referring to FIG. **4**, the inner loop coil **311** may be formed to have a diameter larger by a predetermined distance d than the transmitting coil **110** or the receiving coil **210** and the outer loop coil **312** may be formed to have a diameter larger than the inner loop coil **311**.

[0041] That is, the inner loop coil **311** and the outer loop coil **312** are spaced apart from the transmitting coil **110** or the receiving coil **210** by the predetermined distance d and thus, may be disposed in a concentric shape.

[0042] As illustrated in FIG. **4**, the inner loop coil **311** and the outer loop coil **312** each have opened sides and the opened sides of the inner loop coil **311** and the outer loop coil **312** may be connected to each other to form a single closed loop and the detailed description thereof will be described below.

[0043] The harvesting circuit module **33** receives the energy harvested in the energy harvesting unit **31** and supplies the received energy to loads such as elements, devices, and the like.

[0044] Since the amount of energy harvested in the energy harvesting unit **31** is small, the harvesting circuit module **33** preferably supplies energy to elements or devices having low power consumption, such as a light emitting diode (LED) lamp, and the like. By this operation, the energy efficiency of the overall system can be increased.

[0045] FIG. **5** is a diagram for describing an energy harvesting principle of an apparatus for harvesting leakage energy in accordance with an embodiment of the present invention and FIG. **6** is a diagram for describing an effect of an apparatus for harvesting leakage energy in accordance with an embodiment of the present invention.

[0046] Meanwhile, as described above, the inner loop coil **311** and the outer loop coil **312** configuring the harvesting coil **310** may each have the opened sides. As illustrated in FIG. **4**, each opened side of the inner loop coil **311** and the outer loop coil **312** may be connected to each other to form the single closed loop.

[0047] In this case, the energy harvesting quantity may be in proportion to an area of a closed curved surface formed by the inner loop coil **311** and the outer loop coil **312** to harvest energy as desired by appropriately adjusting the diameter of the inner loop coil **311** and the outer loop coil **312**.

[0048] As described above, the opened sides of the inner loop coil **311** and the outer loop coil **312** are connected to each other to form the single closed loop, which can harvest leakage energy without affecting the wireless power transmission system including the energy transmitting apparatus **10** and the energy receiving apparatus **20**.

[0049] FIG. **5** illustrates a direction of current flowing in each coil when the opened sides of the inner loop coil **311** and the outer loop coil **312** are connected to each other to form the single closed loop.

[0050] Referring to FIG. **5**, provided that current flows in the transmitting coil **110** counterclockwise, current flows in the inner loop coil **311** clockwise that is a direction opposite to the transmitting coil **110** according to a Len's law.

[0051] In this case, the inner loop coil **311** and the outer loop coil **312** are connected to each other in the single closed loop and therefore, current flows in the outer loop coil **312** counterclockwise that is a direction opposite to the inner loop coil **311**.

[0052] The current flowing in a direction opposite to the transmitting coil **110** prevents power from being smoothly transmitted from the transmitting coil **110**. However, in the present invention, current flows in the outer loop coil **312** in the same direction as the transmitting coil **110** and therefore, the influence due to the inner loop coil **311** may be offset, which little affect the power transmission of the transmitting coil **110**.

[0053] FIG. **6** illustrates a direction of current flowing in each coil when harvesting energy using a single loop coil **313** and harvesting energy using two loop coils **314** and **315** that are not connected to each other.

[0054] As illustrated in FIG. **6**A, when using the single loop coil **313**, current flows in the single loop coil **313** in a direction opposite to current flowing in the transmitting coil **110** to prevent the power transmission of the transmitting coil **100**.

[0055] In addition, as illustrated in FIG. **6**B, when using two loop coils **314** and **315** that are not connected to each other, the influence of energy generated from the transmitting coil **110** is dominated and therefore, current flows in both of the two loop coils **314** and **315** that are not connected to each other in a direction opposite to the transmitting coil **110** to prevent the power transmission of the transmitting coil **110**.

[0056] As described above, according to the apparatus for harvesting leakage energy **30** of the present invention, the opened sides of the inner loop coil **311** and the outer loop coil **312** are connected to each other to form the single closed loop, which can harvest the leakage energy without affecting the power transmission of the transmission coil **110**. As a result, the energy efficiency can be increased.

[0057] The effect of the present invention will be described in more detail with reference to FIGS. **7** to **10**.

[0058] FIG. **7** is a graph for describing a change in a resonance frequency of a wireless power transmission system when using an apparatus for harvesting leakage energy in accordance with an embodiment of the present invention and FIG. **8** is a graph for describing a change in a return loss of a wireless power transmission system when using an apparatus for harvesting leakage energy in accordance with an embodiment of the present invention.

[0059] FIG. **9** is a graph for describing a change in an insertion loss of a wireless power transmission system when using an apparatus for harvesting leakage energy in accordance with an embodiment of the present invention and FIG. **10** is a graph for describing a change in loss according to a coupling coefficient between an energy transmitting unit and an energy harvesting unit in a wireless power transmission system when using an apparatus for harvesting leakage energy in accordance with an embodiment of the present invention.

[0060] FIGS. **7** to **10** commonly illustrate calculated simulation values in three cases.

[0061] In each figure of FIGS. **7** to **10**, (a) illustrates the case in which there is no apparatus for harvesting leakage energy **30**, (b) illustrates the case in which the single loop coil **313** is used as illustrated in FIG. **6**A, and (c) illustrates the case in which the apparatus for harvesting leakage energy **30** in accordance with the present invention is used.

[0062] Simulation execution conditions are illustrated in the following Table **1**.

TABLE 1

Common Condition	Transmitting Coil (110)	Diameter 60 cm, 5.5 turns
	Receiving Coil (210)	Diameter 60 cm, 5.5 turns
	Distance Between Transmitting Coil (110) and Receiving Coil (210)	90 cm (Center-Center)
(b)	Harvesting Coil (310)	Diameter 129 cm, 1 turn
	Distance Between Transmitting Coil (110) and Harvesting Coil (310)	34.5 cm (Outermost-Outermost, Based On Vertical Axis)
(c)	Harvesting Coil (310)	Inner Diameter 109 cm, Outer Diameter 129 cm 1 turn
	Distance Between Transmitting Coil (110) and Harvesting Coil (310)	24.5 cm (Outermost-Outermost, Based On Vertical Axis)

[0063] Referring to FIG. **7**, in the case of (b) using the single loop coil **313**, the resonance is generated at 10.70 [MHz] and thus, the resonance frequency is larger changed than (a) in which the resonance is generated at 10.55 [MHz]. However, in the case of (c) in accordance with the embodiment of the present invention, it can be appreciated that there is little difference from (a) in terms of the resonance frequency.

[0064] Similarly, referring to FIGS. **8** and **9**, in the case of (c) in accordance with the embodiment of the present invention unlike (b) using the single loop coil, it can be appreciated that there is little difference from (a) in terms of the return loss and the insertion loss.

[0065] In addition, FIG. **10** illustrates the loss due to the coupling coefficient between the transmitting coil **110** and the harvesting coil **310**. As the loss approximates '0', the coupling coefficient between the transmitting coil **110** and the harvesting coil **310** is increased and thus, more energy is transmitted to the harvesting coil **310** than the receiving coil **210** to be originally transmitted.

[0066] However, as illustrated in FIG. **10**, in the (c) of the embodiment of the present invention, the loss due to the coupling coefficient is about −20 [dB], which corresponds to a value of about 1/100. Therefore, it can be appreciated that the power transmission of the transmitting coil **110** is little affected.

[0067] When the power transmittal is maximal, in the case of (b) using the single loop coil **313**, strong coupling is generated between magnetic field and the loop coil and as a result, the magnetic distribution near the transmitting coil **110** is distorted and energy is not originally transmitted to the receiving coil **210**.

[0068] On the other hand, in the case of (c) in accordance with the embodiment of the present invention, the approximately same magnetic distribution as (a) that does not have the apparatus for harvesting leakage energy **30** is maintained as it is and as a result, the apparatus for harvesting leakage energy **30** in accordance with the embodiment of the present invention little affects the wireless transmission system.

[0069] As described above, according to the apparatus for harvesting leakage energy **30** of the present invention, the energy leaked while the energy radiated from the energy transmitting apparatus **10** of the wireless power transmission system is transmitted to the energy receiving apparatus **20** can be harvested through the harvesting coil **310** in a loop form.

[0070] In addition, the present invention forms the single closed loop by connecting the inner loop coil **311** included in the apparatus for harvesting leakage energy **30** with the opened side of the outer loop coil **312**, thereby harvesting the leakage energy without affecting the performance of the wireless power transmission system.

[0071] In addition, in accordance with the embodiments of the present invention, it is possible to increase the energy efficiency of the overall system by driving the elements or the devices having the low power consumption using the harvested energy.

[0072] Meanwhile, in the embodiment of the present invention, the case in which the harvesting coil **310** harvesting energy is disposed at the transmitting coil **110** side is mainly described, but the position at which the harvesting coil **310** is disposed is not limited thereto and therefore, the harvesting coil **310** can be disposed at the receiving coil **210** side.

[0073] In accordance with the embodiments of the present invention, it is possible to harvest energy leaked while the energy radiated from the energy transmission apparatus of the wireless power transmission system is transmitted to the energy receiving apparatus through the harvesting coil in the loop form.

[0074] Further, in accordance with the embodiments of the present invention, it is possible to harvest the leakage energy without affecting the performance of the wireless power transmission system by forming the single closed loop by connecting the inner loop coil included in the apparatus for harvesting leakage energy with the opened side of the outer loop coil.

[0075] In addition, in accordance with the embodiments of the present invention, it is possible to increase the energy efficiency of the overall system by driving the elements or the devices having the low power consumption using the harvested energy.

[0076] Although the embodiments of the present invention have been described in detail, they are only examples. It will be appreciated by those skilled in the art that various modifications and equivalent other embodiments are possible from the present invention. Accordingly, the actual technical protection scope of the present invention must be determined by the spirit of the appended claims.

What is claimed is:

1. An apparatus for harvesting leakage energy, comprising:

an energy harvesting unit configured to harvest energy leaked while energy radiated from a transmitting unit of an energy transmitting apparatus is transmitted to a receiving unit of an energy receiving apparatus; and

a harvesting circuit module configured to supply energy harvested by the energy harvesting unit to a load.

2. The apparatus of claim **1**, wherein the energy harvesting unit includes:

an inner loop coil configured to be disposed at an outer side of the transmitting unit or the receiving unit and to have an opened side; and

an outer loop coil configured to be disposed at an outer side of the inner loop coil and to have an opened side,

the opened sides of the inner loop coil and the outer loop coil being connected to each other to form a single closed loop.

3. The apparatus of claim **1**, wherein the energy harvesting unit is disposed at the transmitting unit.

4. The apparatus of claim **1**, wherein the energy harvesting unit is disposed at a predetermined distance from the transmitting unit or the receiving unit.

5. The apparatus of claim **1**, wherein the transmitting unit and the receiving unit each are a transmitting coil and a receiving coil.

(57) **ABSTRACT**

A converter includes an inductor configured to receive an input signal and output configured to supply an electrical load with an output signal. The converter operates to charge the inductor until a maximum pre-set current value is reached during a first operating condition in which the electrical load is not supplied. Next, the converter actively supplies the electrical load by partially discharging the inductor during a first time interval of a second operating condition. Then, the converter passively supplies the electrical load by the residual charge of the inductor during a second time interval, subsequent to the first time interval, of the second operating condition, by discharging the inductor completely.

FIG. 13

DC-DC CONVERTER WITH IMPROVED ENERGY MANAGEMENT, METHOD FOR OPERATING THE DC-DC CONVERTER, ENVIRONMENTAL ENERGY HARVESTING SYSTEM USING THE DC-DC CONVERTER, AND APPARATUS USING THE ENERGY HARVESTING SYSTEM

PRIORITY CLAIM

[0001] This application claims priority from Italian Application for Patent No. TO2014A000059 filed Jan. 28, 2014, the disclosure of which is incorporated by reference.

TECHNICAL FIELD

[0002] The disclosure relates to a DC-DC converter with improved energy management and to a method for operating the DC-DC converter. The disclosure further relates to an environmental energy harvesting system comprising the DC-DC converter and to an apparatus comprising said environmental energy harvesting system.

BACKGROUND

[0003] As is known, systems for harvesting energy (also known as "energy scavenging systems") from intermittent environmental energy sources (i.e., ones that supply energy in an irregular way) have aroused and continue to arouse considerable interest in a wide range of fields of technology. Typically, energy harvesting systems are configured to harvest, store and transfer energy generated by mechanical or thermal sources to a generic load of an electrical type.

[0004] Low-frequency vibrations, such as, for example, mechanical vibrations of disturbance in systems with moving parts may be a valid source of energy. The mechanical energy is converted, by one or more appropriate transducers (for example, piezoelectric or electromagnetic devices) into electrical energy, which may be used for supplying an electrical load. In this way, the electrical load does not require batteries or other supply systems that are cumbersome and present a low resistance in regard to mechanical stresses.

[0005] FIG. **1** is a schematic illustration in the form of functional blocks of an energy harvesting system of a known type.

[0006] The energy harvesting system **1** of FIG. **1** comprises: a transducer **2**, for example of an electromagnetic or piezoelectric type, subject in use to environmental mechanical vibrations and configured to convert mechanical energy into electrical energy, typically into AC (alternating current) voltages; a scavenging interface **4**, for example comprising a diode-bridge rectifier circuit (also known as Graetz bridge), configured to receive at input the AC signal generated by the transducer **2** and supplying at output a DC (direct current) signal for charging a capacitor **5** connected to the output of the rectifier circuit **4**; and a DC-DC converter **6**, connected to the capacitor **5** for receiving at input the electrical energy stored by the capacitor **5** and supplying it to an electrical load **8**. Thus, the capacitor **5** has the function of element for storing energy, which is made available, when required, to the electrical load **8** for operation of the latter.

[0007] The transducer **2** is, for example, an electrochemical transducer, or an electromechanical transducer, or an electroacoustic transducer, or an electromagnetic transducer, or a photoelectric transducer, or an electrostatic transducer, or a thermoelectric transducer.

[0008] The main disadvantage of the configuration according to FIG. **1** regards the fact that the maximum voltage supplied at output by the scavenging interface **4** is limited by the input dynamics of the DC-DC converter **8**.

[0009] In applications in which the transducer **2** converts mechanical energy into electrical energy in a discontinuous way and/or the power P_{LOAD} required by the electrical load **8** varies significantly in time, also the voltage V_{OUT} consequently has an evolution variable in time. This causes, for example, a variation of the efficiency factor of the DC-DC converter **6**, which is inversely proportional to the value assumed by V_{OUT}. The maximum value of V_{OUT} is further limited by the range of input voltages accepted by the DC-DC converter.

[0010] European Patent reference No. EP 2518878 (incorporated by reference) describes a DC-DC converter with a high efficiency factor even in conditions of light load and wide dynamic range of the input voltage. According to this reference, it is important to monitor the inductor current to prevent it from assuming negative values (i.e., to prevent energy from being absorbed by the electrical load). For this purpose, according to the reference, a current-detection circuit is provided, which constantly monitors the inductor current and uncouples the electrical load from the inductor when the current monitored assumes the zero value. A solution of this type requires, in the design step, an accurate trade-off between the desired accuracy of the measurement supplied by the current-detection circuit and the consumption of current of said current-detection circuit.

[0011] It is consequently desirable to have available a DC-DC converter that will enable management, in an efficient and, at the same time, accurate way, of supply of the electrical load connected thereto, preventing the DC-DC converter from absorbing energy from the load itself. It is likewise desirable for the management of supply of the load to be carried out automatically and with low current consumption.

SUMMARY

[0012] In an embodiment, a DC-DC converter is provided with improved energy management, a method for operating the DC-DC converter is provided, an energy harvesting system comprising the DC-DC converter is provided and an apparatus comprising the energy harvesting system that will enable the aforementioned advantages to be achieved is provided. In particular, the DC-DC converter enables a high efficiency factor to be maintained even in conditions of light load (e.g., 10 μW-100 μW) and of variable input and output voltages (e.g., 0.25 V-5 V at input, 1 V-5 V at output), minimizing the power consumption of the DC-DC converter.

BRIEF DESCRIPTION OF THE DRAWINGS

[0013] For a better understanding of the present invention, preferred embodiments thereof are now described, purely by way of non-limiting example and with reference to the attached drawings, wherein:

[0014] FIG. **1** shows an energy harvesting system of a known type;

[0015] FIG. **2** is a schematic illustration of a DC-DC converter;

[0016] FIGS. **3**A-**3**D show the converter of FIG. **2** in successive operating steps;

[0017] FIGS. **4**A-**4**D show the evolution of the inductor current in the DC-DC converter of FIG. **2**;

[0018] FIGS. **5**-**8** show respective circuits belonging to the converter of FIG. **2** for control of the inductor current in order to implement, respectively, the steps of FIGS. **4A**-**4D**;

[0019] FIG. **9** shows a circuit for driving the converter of FIG. **2** used during the steps of FIGS. **3A**-**3D**;

[0020] FIGS. **10A**-**10C** show driving signals used during operation of the driving circuit of FIG. **9**;

[0021] FIG. **11** shows an embodiment of the DC-DC converter comprising a control logic;

[0022] FIG. **12** shows steps of a method implemented by the control logic of FIG. **11** for operating the DC-DC converter, in order to implement the steps of FIGS. **3A**-**3D** and **4A**-**4D**; and

[0023] FIG. **13** shows an environmental energy harvesting system comprising the DC-DC converter of FIG. **2** or FIG. **11**.

DETAILED DESCRIPTION OF THE DRAWINGS

[0024] FIG. **2** is a schematic illustration of a converter **10**, in particular configured to carry out a DC-DC conversion, of a buck-boost type, comprising an inductor **18** coupled to the input of the converter **10** and at least one output for supplying a respective load **20**. This type of converter is also known as SISO (single-inductor single-output) converter. It is evident that, according to a different embodiment, the converter **10** may be of a SIMO (single-inductor multiple-output) type, having a plurality of outputs configured to supply a respective plurality of electrical loads.

[0025] For simplicity of description, in what follows reference will be made to a converter of a SISO type, without this implying any loss of generality.

[0026] In the description, reference will be made indifferently to switches “open” or “OFF” to indicate that said switches do not conduct electric current and, in the case of transistors, have their control terminal (e.g., the gate terminal) biased in such a way as not to conduct electric current between the source and drain terminals. Further, reference will be made indifferently to switches “closed” or “ON” to indicate that said switches conduct electric current and, in the case of transistors, have their control terminal (e.g., the gate terminal) biased in such a way as to conduct electric current between the source and drain terminals.

[0027] In greater detail, the converter **10**, comprises a main bridge **12**, including a supply terminal **12***a* at a voltage V_{IN} (with V_{IN} ranging, for example, between 0.25 V and 5 V) and a reference terminal GND (connected to ground; however, other reference voltages may be used, for example $-V_{IN}$). The main bridge **12** further includes a high-side switch **13** and a low-side switch **14**, connected together in series between the supply terminal **12***a* and the ground reference terminal GND. In particular, the high-side switch **13** is directly connected to the supply terminal **12***a* for receiving the signal V_{IN} and the low-side switch **14** is directly connected to the ground reference terminal GND.

[0028] According to one embodiment, as shown in FIG. **2**, the high-side switch **13** is a MOSFET, in particular an n-channel double-diffusion MOS (DMOS) transistor, with an ON-resistance (R_{ON}) of approximately 0.2Ω at 100 mA. The low-side switch **14** is of the same type as the transistor **13**. Alternatively, in a way not shown, the high-side switch **13** and the low-side switch **14** may be produced using a different technology, for example they may be p-channel MOSFETs, or NPN or PNP bipolar transistors, IGBTs, or simply diodes.

[0029] Once again with reference to FIG. **2**, a diode **15** and a diode **16** are connected between a respective source terminal S and a respective drain terminal D of the high-side switch **13** and of the low-side switch **14**. The diodes **15** and **16** are connected in configuration known as “antiparallel” (with respect to the normal direction of flow of the current through the high-side switch **13** and the low-side switch **14**). As is known, a characteristic of a MOSFET is that of presenting, in certain operating conditions, the electrical properties of a diode (parasitic diode). Said diode is electrically set (integrated) between the source and drain terminals of the MOSFET. In other words, the high-side switch **13** and the low-side switch **14** may present the electrical behavior of a diode, in which the cathode of the diode corresponds to the drain terminal and the anode to the source terminal of the respective high-side switch **13** and low-side switch **14** (vice versa, in the case of MOSFETs of a p type). In greater detail, the drain terminal D of the high-side switch **13** is connected to the supply terminal **12***a*, the source terminal S of the high-side switch **13** is connected to the drain terminal of the low-side switch **14** and the source terminal S of the low-side switch **14** is connected to the ground reference terminal GND. The high-side switch **13** and low-side switch **14** are driven in conduction by a respective first driving circuit **25** and second driving circuit **26**, which are described more fully hereinafter. The driving circuits **25**, **26** are connected to the control terminal G (or gate terminal) of the transistors that form the high-side switch **13** and the low-side switch **14**, respectively.

[0030] The DC-DC converter **10** further comprises an inductor **18**, having an inductance L for example comprised between approximately 1 μH and approximately 100 μH, in particular 10 μH. The inductor **18** includes a first conduction terminal **18***a* connected between the high-side switch **13** and the low-side switch **14** (in particular, connected to the source terminal S and drain terminal D of the high-side switch **13** and of the low-side switch **14**, respectively) and a second terminal **18***b*, connected to the output bridge of the converter **10**. The second terminal **18***b* is electrically coupled to the electrical load **20** by a coupling switch **22** and may be electrically connected to the reference terminal GND by a charge switch **23**. Further, a diode **24** is connected in parallel to the coupling switch **22**, with the anode coupled to the terminal **18***b* of the inductor **18** and the cathode coupled to the load **20**. According to one embodiment, which in no way limits the scope of the present invention, the coupling switch **22** is a p-channel MOSFET. The diode **24** is the parasitic diode set (integrated) between the source and drain terminals of the MOSFET. In other words, when the coupling switch **22** is OFF, it assumes the electrical behavior of a diode, in which the cathode of the diode corresponds to the source terminal and the anode to the drain terminal of the coupling switch **22**.

[0031] As is described more fully hereinafter, the coupling switch **22** has the function of enabling transfer of the energy stored in the inductor **18** towards the load **20** (coupling switch **22** ON, condition of load supplied and of the inductor current I_L discharged on the output), or else of insulating electrically the load **20** from the inductor **18** (coupling switch **22** OFF, condition of load not supplied in an active way). The presence of the diode **24**, with the cathode facing the load **20**, does not allow transfer of energy from the electrical load **20** to the inductor **18** when the coupling switch **22** is OFF, but instead allows transfer of current in a passive way from the inductor **18** to the electrical load **20** when the coupling switch **22** is OFF and the diode **24** is appropriately biased.

[0032] The electrical load **20** may, for example, require a value of supply voltage V_{OUT} comprised between 1 V and 5 V, or other values still, according to the application, for example sensors of various types, microcontrollers and communication systems.

[0033] In use, the energy required by the electrical load **20** for its operation is, as has been anticipated, supplied by the inductor **18**, which, in turn, is charged and discharged by appropriately controlling the high-side switch **13** and the low-side switch **14** of the main bridge **12** and the switches **23** and **24** of the secondary output bridge. The high-side switch **13** and the low-side switch **14** are driven (opened/closed; turned on/turned off) in such a way as to prevent a direct connection between the terminal **12***a* at the supply voltage V_{IN} and the ground reference terminal GND. Reference may be made for this purpose to FIGS. **9** to **10**C, which are described hereinafter.

[0034] The converter **10** further comprises, in parallel to the charge switch **23**, electrically coupled between the terminal **18***b* of the inductor **18** and the ground reference terminal GND, an anti-oscillation switch **58**, operation of which is described more fully with reference to FIG. **3**D.

[0035] According to one embodiment, both the charge switch **23** and the anti-oscillation switch **58** are transistors, for example n-channel MOSFETs.

[0036] FIGS. **3**A-**3**D show respective operating steps of the converter **10** of FIG. **2** for implementing a method of control of the primary bridge and of the secondary bridge for charging and discharging the inductor **18** during each step of supply of the load **20**.

[0037] For simplicity of representation, all the switches are represented using the graphic symbol of a generic switch and not as MOSFETs. For the same reason, also the respective diodes have been omitted, except for the diode **24**.

[0038] FIGS. **4**A-**4**D show time plots of the variation of the energy (in particular, the variation of the current I_L) in the inductor **18** during each of the operating steps of FIGS. **3**A-**3**D, respectively.

[0039] With reference to FIG. **3**A, in this initial step the inductor **18** is in a discharged state and has to be charged. For this purpose, the high-side switch **13** of the main bridge **12** is closed, whereas the low-side switch **14** is open. Further, in this step, also the charge switch **23** is closed, thus coupling the terminal **18***b* of the inductor **18** to the ground reference terminal GND. The anti-oscillation switch **58** is, instead, open. With joint reference to FIGS. **3**A and **4**A, a current flows between the supply terminal **12***a*, biased at a voltage V_{IN} and the ground reference terminal GND, through the inductor **18**, which is thus energized (charged). Reference may be made to FIG. **4**A, which shows a curve representing the evolution of the current I_L stored in the inductor **18** during the step of FIG. **3**A. The current I_L increases, in a substantially linear way, starting from a minimum value I_0 (in particular the zero value, or a value close to zero) until it reaches a maximum value I_{Lmax}, in a time interval comprised between the instants t_1 and t_{1a}. The maximum value I_{Lmax} is a predefined value, chosen on the basis of the characteristics of the inductor **18** used and on the basis of the electrical load to be supplied, for example 100 mA.

[0040] The step of FIG. **3**A terminates when the energy stored in the inductor **18** reaches the predefined maximum value (current $I_L = I_{Lmax}$).

[0041] The next step is represented in FIG. **3**B. With reference to this figure, the high-side switch **13** and the charge switch **23** are opened, whereas the low-side switch **14** is closed. Opening of the high-side switch **13** is preferably carried out prior to closing of the low-side switch **14**. There is thus prevented direct connection of the supply terminal **12***a* to the ground reference voltage GND, thus avoiding phenomena of cross conduction between the terminal **12***a* and the ground reference terminal GND.

[0042] Then, once again with reference to FIG. **3**B, the coupling switch **22** is closed, thus connecting the load **20** to the terminal **18***b* of the inductor **18**. The terminal **18***a* of the inductor **18** is connected to the ground reference terminal GND via the low-side switch **14** and the energy stored in the inductor **18** flows towards the load **20**, thus supplying it.

[0043] With reference to FIG. **4**B, in this step of supply of the load, the current I_L in the inductor **18** decreases until it reaches a predefined low value I_{RES}, at time t_2. The predefined low value I_{RES} is not the zero value of the current I_L, but a value comprised, for example, between 5% and 20% of the peak value I_{Lmax}.

[0044] Then, FIG. **3**C, the coupling switch **22** is opened and the low-side switch **14** is kept closed. The diode **24** continues to conduct electric current, in so far as, in this situation, it is forward biased. The residual current stored in the inductor **18** consequently continues to flow towards the load **20**, through the diode **24** until it reaches the zero value. This condition is illustrated in FIG. **4**C, which shows the decrease of the current I_L from the value I_{RES} to the value I_0 (zero current value), at time t_3. This step is a step of passive transfer of the energy towards the load **20**.

[0045] During passive transfer of charge from the inductor **18** to the electrical load **20**, the transistor that constitutes the coupling switch **22** is OFF and transfer of charge takes place via the diode integrated in the transistor **22** (in the figures, this is the diode designated by the reference number **24**). Discharge of the inductor current is a function of the output supply voltage V_{OUT} and of a difference of potential across the coupling switch **22**, corresponding to the voltage V_{BE} across the diode **24**.

[0046] The next step is represented in FIG. **3**D. Here, the anti-oscillation switch **58** (which up to now was open) is driven into a closed state, whereas the switch **23** is kept open. Both of the terminals **18***a* and **18***b* of the inductor **18** are thus coupled to the ground reference terminal GND. In this way, any spurious voltage oscillations on the terminals **18***a* and **18***b*, caused by residual energy possibly stored in the inductor **18** and in the parasitic capacitors associated to the terminals **18***a* and **18***b*, are prevented. In fact, any possible undesirable oscillations may cause problems of an electromagnetic nature, in addition to a possible reduction of the global efficiency of the converter **10**.

[0047] With reference to FIG. **4**D, it may be noted that the current I_L in the inductor **18** drops to negative values (i.e., in the inductor **18** a current flows from the terminal **18***b* to the terminal **18***a*) and settles, at time t_4, to the value I_0.

[0048] Then, the cycle of complete charge and discharge of the inductor **18** may restart, if necessary, for supplying the load **20** one again (i.e., the cycle returns to the step of FIGS. **3**A, **4**A).

[0049] The duration of the time interval t_1-t_{1a}, in what follows referred to as interval T_{ON}, is not predefined, but is calculated in an appropriate way so that, as the supply voltage V_{IN} varies, the interval T_{ON} will always enable charging of the inductor **18** to the desired maximum value I_{Lmax}. In other words, a voltage V_{IN} of a high value will charge the inductor

18 in a short time interval T_{ON}; instead, a voltage V_{IN} of a low value will charge the inductor **18** in a longer time interval T_{ON}.

[0050] With reference to FIG. **2**, the function of definition of the appropriate interval T_{ON} is performed by the first adaptive control block **51**, electrically coupled to the supply terminal **12***a* for receiving the voltage V_{IN} on the basis of which the length of the interval T_{ON} is to be determined in an adaptive way.

[0051] FIG. **5** shows, according to one embodiment, a circuit implementation of the first adaptive control block **51**, for calculation of T_{ON}.

[0052] The first adaptive control block **51** comprises a branch **52** including a resistive voltage divider formed by a resistor **54** having a resistance R of 6 MΩ and by a resistor **56**, connected in series to the first resistor **54**, having a resistance equal to R/2, i.e., 3 MΩ. The resistors **54** and **56** are connected together in series. In particular, the resistor **54** has a first terminal coupled to V_{IN} and a second terminal coupled to an intermediate node **55**; the resistor **56** has a first terminal **56***a* coupled to the intermediate node **55** and a second terminal that may be coupled to the ground reference terminal GND. Electrical coupling and uncoupling of the second terminal of the resistor **56** to the ground reference terminal GND is managed by a switch **57** (e.g., a MOSFET), connected in series to the second resistor **56** between the second terminal and the ground reference terminal GND. The switch **57** is in a closed state during the operating steps of the adaptive control block **51** and is opened when the converter **10** is OFF or when the adaptive control block **51** is not functioning in order to prevent any undesirable dissipation of current. The switch **57** may, however, not be present.

[0053] An amplifier **60** includes a non-inverting input **60***a* electrically coupled to the intermediate node **55**, configured to receive, in use, a voltage substantially equal to $V_{IN}/3$ (assuming, for simplicity, that the resistance introduced by the switch **58** is ideally substantially zero). The inverting terminal **60***b* of the amplifier **60** is connected to the ground reference terminal GND through a resistor **62** having a resistance R_{ON}=3 MΩ. The output terminal **60***c* of the amplifier **60** is configured to bias the gate terminal of a transistor, e.g. an n-channel MOSFET, **64**. Further, the source terminal S of the transistor **64** is electrically coupled to the inverting terminal **60***b* and, via the resistor **62**, to the ground reference terminal GND.

[0054] At the instant t_1 (see FIG. **4**A), when it is desired to start charging of the inductor **18**, the switch **57** is closed. In this way, the non-inverting terminal **60***a* is biased at a voltage equal to $V_{IN}/3$, as indicated previously. The output **60***c* of the amplifier **60** assumes a value such as to bias the gate of the transistor **64**, which starts to conduct an electric current $i_1=V_{IN}/(IR_{ON})$. In practice, the stage formed by the amplifier **60**, the transistor **64** and the resistor **62** forms a voltage-to-current converter.

[0055] The drain terminal of the transistor **64** is connected to a supply terminal **80** at a voltage V_{DD} (e.g., comprised between approximately 2 V and approximately 5 V, for example approximately 3.5 V) via a transistor **79**. The voltage V_{DD} is, for example, supplied by a battery, not shown in the figure. The transistor **79** comprises a source terminal connected to the supply terminal **80** and a drain terminal and gate terminal connected together and to the drain terminal of the transistor **64**. A further transistor **82** is connected in current-mirror configuration **83** with the transistor **79**. In particular, the transistor **82** comprises a gate terminal connected to the gate terminal of the transistor **79** and a source terminal connected to the supply terminal **80**. The current mirror **83** has a gain ratio 1:M and has the function of generating a current i_2, through the transistor **82**, of a value $i_2=M\cdot i_1$. According to one embodiment, the value of M is chosen equal to 8 and is obtained by sizing appropriately the transistor **82**, in a per se known manner.

[0056] The first adaptive control block **51**, thus, converts the input voltage V_{IN} into a current signal i_2 that is inversely proportional to the voltage V_{IN}.

[0057] The current signal i_2 is used for charging a capacitor **84** (current signal i_{C_ON}).

[0058] As may be noted from FIG. **5**, the drain terminal of the transistor **82** is connected to the ground reference terminal GND by a pair of transistors **76**, **78**. The transistor **76** is a p-channel MOSFET, whereas the transistor **78** is an n-channel MOSFET and, together, constitute a current-limited inverter.

[0059] The transistors **76**, **78** have their respective gate terminals coupled to the same terminal α for receiving an enable signal S_{EN_ON}. The enable signal S_{EN_ON} is a binary signal configured to assume two values: a "high" value configured to turn on the transistor **78** and, at the same time, to turn off the transistor **76**; and a "low" value configured to turn off the transistor **78** and, at the same time, to turn on the transistor **76**. In a way evident to a person skilled in the branch, the "high" and "low" values are chosen appropriately on the basis of the biasing characteristics of the transistors **76**, **78** used and it is possible to envisage use of an appropriate buffer for adequately biasing the gates of the transistors **76** and **78**.

[0060] In use, during the step of charging of the inductor **18** (FIGS. **3**A, **4**A) it is expedient to monitor the time interval T_{ON} in order for the inductor **18** to be charged up to the required maximum value I_{Lmax}. For this purpose, at time t_1, the enable signal S_{EN_ON} assumes a low value for turning on the transistor **76** and turn off the transistor **78**. The current i_2 thus flows from the supply terminal **80**, through the transistors **82** and **76**, to the capacitor **84**, thus charging it with a current $i_{C\_ON}=i_2$.

[0061] The first adaptive control block **51** further comprises a comparator **86**, configured to receive on its inverting terminal the value of voltage across the capacitor **84** and, on its non-inverting terminal, a reference signal S_{REF_ON} (voltage signal). Said reference value S_{REF_ON} is chosen in such a way that the time of charging of the capacitor **84**, from a zero value to a value S_{REF_ON}, is equal to the desired value for the interval T_{ON}. In this way, the time taken by the capacitor **84** to be charged up to the value S_{REF_ON} is the interval T_{ON}, which is inversely proportional to the input voltage V_{IN}. The interval T_{ON} may thus be determined directly on the basis of the time taken by the capacitor **84** to reach the value S_{REF_ON} starting from a discharged condition of the capacitor **84**.

[0062] According to one embodiment, the reference value S_{REF_ON}, is equal to approximately 1 V. The signal S_{REF_ON} is, as has been said, a voltage reference signal and is generated in a per se known manner, for example by a reference-signal-generator block **90**. The reference-signal-generator block **90** is connected between the supply terminal **80**, for receiving the voltage V_{DD} and the ground reference terminal GND. The supply voltage V_{DD} is applied across a branch including a Zener diode **91** set in series with a resistor **92**. In greater detail, the anode of the Zener diode **91** is connected to ground

GND, the cathode of the Zener diode **91** is connected to a terminal of the resistor **92** and the other terminal of the resistor **92** is connected to the supply terminal **80**. The reference signal S_{REF_ON} is taken at the cathode of the Zener diode **91**. Operation of the reference-signal-generator block **90** is in itself evident. The Zener diode **91** operates as voltage limiter and the resistor **92** has the function of introducing a biasing current in the Zener diode **91**. The value of the resistance **92** is to be calculated on the basis of the specific requirements, i.e., as a function of the effective value of the biasing current of the Zener diode **91**. To obtain the effective value of resistance of the resistor **92** it is sufficient to use the formula $(V_{DD}-V_Z)/i_A$, where V_{DD} is the supply voltage, V_Z is the operating voltage of the Zener diode **91** and i_A is the current of absorption of the block **90** (absorption of the Zener diode **91**). The value of V_Z defines, as is evident, the voltage value desired for reference signal S_{REF_ON} (a Zener diode **91** with an operating voltage equal to the value desired for the reference S_{REF_ON} will be used).

[0063] According to one embodiment, the capacitor **84** is a variable-capacitance capacitor. In this way, at the end of the steps of manufacture of the DC-DC converter **10**, i.e., during a step of testing of the DC-DC converter **10**, it is possible to set a desired value of capacitance of the capacitor **84**, which may have undergone variations on account of process spread. According to one embodiment, the value of capacitance C_{ON} of the capacitor **84** is chosen and set at 900 fF.

[0064] The comparator **86** is, in particular, a hysteretic comparator, configured to generate a hysteresis around the value set by the reference signal S_{REF_ON}, for example a hysteresis interval of approximately 20 mV. This is useful in order to compensate for possible undesirable variations of the signals involved in the comparison step.

[0065] The comparator **86** is configured to generate at output a comparison signal S_{CMP_ON}, configured to assume two values: a "low" value (logic value "0") at time t_{1a} (which identifies the end of the interval T_{ON}); and a "high" value (logic value "1") otherwise.

[0066] In use, when the voltage across the capacitor **84** reaches the value set by the reference signal S_{REF_ON}, the comparison signal S_{CMP_ON} changes state (e.g., passing from a high logic value to a low logic value), thus indicating that the current in the inductor has reached the maximum value I_{Lmax}. The next step is represented in FIGS. **3**B, **4**B. During this step (and during the subsequent steps) the capacitor **84** is discharged completely. For this purpose, the enable signal S_{EN_ON} assumes a "high" value, such as to turn off the transistor **76** and turn on the transistor **78**. The capacitor **84** has, in this condition, both of the terminals coupled to the ground reference terminal GND and discharges. The comparison signal S_{CMP_ON} once again assumes the high logic value.

[0067] The comparison signal S_{CMP_ON} thus generated is used for determining the end of the interval T_{ON} and consequently a falling edge thereof determines turning-off of the high-side switch **13**. In this way, the duration of the interval T_{ON} varies as a function of the value of the input voltage V_{IN} in so far as the time of charging of the capacitor **84** is inversely proportional to the value of the input voltage V_{IN}. Consequently, once the value S_{REF_ON} is appropriately fixed, the peak current I_{Lmax} stored in the inductor **18** assumes a value that is always constant, even as V_{IN} varies. The time interval T_{ON} during which the inductor **18** is being charged assumes, instead, a value variable according to the value of input voltage V_{IN} (which is inversely proportional to V_{IN}) or, rather, according to the value assumed by the current signal i_2, which is proportional to the current signal i_1 generated starting from the voltage value V_{IN}.

[0068] In greater detail, it is found that the value of current $i_{C\_ON}=i_2$ is equal to $(M\cdot V_{IN})/(3R_{ON})$, where R_{ON} is the resistance of the resistor **62** and M is the value of current gain of the current mirror **83** (e.g., M=8). Consequently, we have that the value of the interval T_{ON} is equal to $(3R_{ON}\cdot C_{ON}\cdot S_{REF\_ON})/(M\cdot V_{IN})$, where C_{ON} is the value of capacitance of the capacitor **84**.

[0069] The value I_{Lmax} is given by $(T_{ON}\cdot V_{IN})/L$, where L is the value of inductance of the inductor **18**. It follows that the predefined maximum value I_{Lmax} for the current I_L stored in the inductor **18** is irrespective of the value of the input voltage V_{IN} and is given by

$$I_{Lmax}=(3R_{ON}\cdot C_{ON}\cdot S_{REF\_ON})/(M\cdot L)$$

[0070] To return to FIG. **2**, the converter **10** further comprises a second adaptive control block **101**, configured to generate a discharge time interval T_{OFF} during which the step described with reference to FIGS. **3**B and **4**B is carried out. During the discharge time interval T_{OFF} the charge stored in the inductor **18** flows to the load **20**, thus supplying it. As has been said, this step of discharge (active discharge) occurs between the time t_{1a} and the time t_2 by driving the coupling switch **22** in conduction (transistor ON); a subsequent step of passive discharge occurs by opening the switch **22** (transistor OFF) and causing flow of the residual charge through the diode **24**. The discharge time interval T_{OFF} is an interval during which there is a process of active discharge of the inductor **18** (i.e., using active elements, namely, the transistor that constitutes the switch **22**). During the step of active discharge, the output supply signal V_{OUT} is applied also to the node **18***b* of the inductor, since the coupling switch **22** is ON.

[0071] With reference to FIG. **6**, the second adaptive control block **101** comprises an input branch **102** connected between the load **20** and the ground reference terminal GND. The input branch **102** comprises, connected in series together, a resistor **104**, having a resistance R_{OFF}, for example equal to 9 MΩ, a transistor **105**, of an n-channel type and a transistor **106**, of an re-channel type.

[0072] The resistor **104** has one conduction terminal coupled to the supply voltage for supply of the load **20** and the other conduction terminal coupled to the drain terminal of the transistor **105**. In turn, the transistor **105** has its source terminal coupled to the drain terminal of the transistor **106** and the latter has its source terminal electrically coupled to the ground reference terminal GND.

[0073] According to the embodiment shown in FIG. **6**, a switch **103** is set in series to the resistor **104**, between the resistor **104** and the transistor **105**. During operation of the second adaptive control block **101**, this switch **103** is in a closed state (i.e., it conducts current). When the second adaptive control block **101** is not used, or when the converter **10** is OFF, the switch **103** is open (i.e., it does not conduct). The switch **10** is optional and is configured to guarantee selective electrical insulation of the second adaptive control block **101** in order to prevent undesirable consumption of current when the converter **10** is OFF or when the second adaptive control block **101** is not used.

[0074] In greater detail, the transistor **105** forms, together with a further transistor **108**, a current mirror **107**. Also the transistor **106** forms, together with a further transistor **110**, a respective current mirror **109**. For this purpose, the gate terminal of the transistor **105** is electrically connected to the gate terminal of the transistor **108**; further, the drain terminal of the transistor **105** is electrically connected to the gate terminals of the transistors **105** and **108**. Likewise, the gate terminal of the transistor **106** is electrically connected to the gate terminal of the transistor **110**; further, the drain terminal of the transistor **106** is electrically connected to the gate terminals of the transistors **106** and **110**.

[0075] The transistors **108** and **110** are connected together in series on an intermediate branch **112** of the adaptive control block **101**. The intermediate branch **112** further comprises a p-channel transistor **114** connected between the drain terminal of the transistor **108** and a supply terminal (the latter, in particular, coinciding with the supply terminal **80** shown in FIG. **5** and being supplied by the voltage V_{DD} itself). In greater detail, the source terminal of the transistor **114** is connected to the voltage V_{DD}, the drain terminal of the transistor **114** is connected to the drain terminal of the transistor **108**, the source terminal of the transistor **108** is connected to the drain terminal of the transistor **110** and the source terminal of the transistor **110** is connected to the ground reference terminal GND. Further connected between the drain terminal of the transistor **110** and the ground reference terminal GND (i.e., in parallel to the transistor **110**) is a resistor **116**, which has, for example, a value of resistance equal to $R_{OFF}/2$.

[0076] In use, when an output voltage V_{OUT} is present on the terminal **18***b*, we have that a current i_{OFF_IN} flows on the input branch **102**, through the resistor **104** and the transistors **105**, **106**. The voltage drop on the resistor **104** is thus equal to $V_{OUT}-2V_{GS}$, where V_{GS} is the voltage drop between gate and source terminals of each of the transistors **105** and **106**, which are assumed as being the same as one another. The current t_{OFF_IN} is thus given by

$$i_{OFF\_IN}=(V_{OUT}-2V_{GS})/R_{OFF}$$

[0077] On the basis of operation of the current mirrors **107** and **109** we have that the current i_{INT} that flows in the intermediate branch **112** is equal to $i_{OFF\_IN}+2V_{GS}/R_{OFF}$, where, also in this case, V_{GS} is the voltage drop between the gate and source terminals of the transistor **110**, which is assumed as being the same as the transistors **105** and **106** and thus as having the same voltage V_{GS}. As a result of operation of the current mirrors **107** and **109** and of the presence of the resistor **116** with resistance $R_{OFF}/2$, we thus have: $i_{INT}=V_{OUT}/R_{OFF}$; namely, the current that flows in the intermediate branch **112** is irrespective of the voltages V_{GS} of the transistors belonging to the current mirrors **107** and **109** (which are assumed as being the same as one another).

[0078] The second adaptive control block **101** further comprises an additional current mirror **116**, formed by the transistor **114** (belonging to the intermediate branch **112**) and by a transistor **118**, of a p-channel type, which belongs to an output branch **122**.

[0079] The transistors **114** and **118** have their respective source terminals connected to the supply terminal **80** and respective gate terminals connected together and to the drain terminal of the transistor **114**. The current mirror **116** has a gain ratio 1:N and has the function of generating a current i_{OFF_OUT} of a value $N\cdot i_{INT}$. According to one embodiment of the present invention, the value of N is chosen equal to 10 and is obtained by appropriately sizing the transistor **118** in a per se known manner.

[0080] The output branch **122** further comprises a pair of transistors **126**, **128**. The transistor **126** is a p-channel MOSFET, whereas the transistor **128** is an n-channel MOSFET and, together, provide a current-limited inverter.

[0081] The transistors **126**, **128** have their respective gate terminals coupled to the same terminal β for receiving an enable signal S_{EN_OFF}. The enable signal S_{EN_OFF} is a signal configured to assume two values: a "high" value configured to turn on the transistor **128** and, at the same time, to turn off the transistor **126**; and a "low" value configured to turn off the transistor **128** and, at the same time, to turn on the transistor **126**. In a way evident for the person skilled in the branch, the "high" and "low" values are chosen appropriately on the basis of the biasing characteristics of the transistors **126**, **128** used.

[0082] In use, during the step of active discharge of the inductor **18** (FIGS. 3B, 4B) it is expedient to manage the time interval T_{OFF} so that the inductor **18** will be discharged to the intermediate value I_{RES} envisaged. For this purpose, at time t_{1a}, the enable signal S_{EN_OFF} assumes a low logic value, thus turning on the transistor **126** and turning off the transistor **128**. The current i_{OFF_OUT} thus flows from the supply terminal **80**, through the transistors **118** and **126**, to the capacitor **134**, charging it with a current $i_{C\_OFF}=i_{OFF\_OUT}$.

[0083] The second adaptive control block **101** further comprises a comparator **136**, which is configured to receive on the inverting terminal the value of voltage across the capacitor **134** and, on the non-inverting terminal, a reference signal S_{REF_OFF} (voltage signal) configured to set a maximum voltage value that the voltage across the capacitor **134** may assume. Said reference value S_{REF_OFF} is chosen in such a way that the time of charging of the capacitor **134** from the value that it assumes when it is discharged to the reference value S_{REF_OFF} is equal to the value desired for the interval T_{OFF}. In this way, the time taken by the capacitor **134** to charge up to the reference value S_{REF_OFF} corresponds to the interval T_{OFF}.

[0084] According to one embodiment, the reference value S_{REF_OFF}, is approximately 1 V. The signal S_{REF_OFF} is, as has been said, a voltage reference signal and is generated in a per se known manner, for example by a reference-signal-generator block similar to the reference-signal-generator block **90** of FIG. **5** and thus not described any further.

[0085] The capacitor **134** is, according to one embodiment, a variable-capacitance capacitor. In this way, at the end of the steps of manufacture of the DC-DC converter **10**, i.e., during a step of testing of the DC-DC converter **10**, it is possible to set a desired value of capacitance of the capacitor **134**, which may have undergone variations on account of process spread. According to one embodiment, the value of capacitance C_{OFF} of the capacitor **134** is chosen and set at 900 fF.

[0086] The comparator **136** is, in particular, a hysteretic comparator, configured to generate a hysteresis around the reference value S_{REF_OFF}, for example a hysteresis interval of approximately 10 mV. This is useful in order to compensate for possible undesirable variations of the signals involved in the comparison step.

[0087] The comparator **136** is configured to generate at output a comparison signal S_{CMP_OFF}, configured to assume two values: a "low" value (logic value "0") at time t_2 (i.e., the time that indicates the end of the interval T_{OFF}); and a "high" value (logic value "1") otherwise.

[0088] In use, when the voltage across the capacitor **134** reaches the reference value S_{REF_OFF}, the comparison signal S_{CMP_OFF} changes state (e.g., passing from the high logic value to the low logic value), thus indicating that the current in the inductor has reached the intermediate value I_{RES}. The next step is represented in FIGS. **3**C, **4**C. During this step (and during the subsequent steps) the capacitor **134** is discharged completely. For this purpose, the enable signal S_{EN_OFF} assumes a "high" value, such as to turn off the transistor **126** and turn on the transistor **128**. The capacitor **134** has, in this condition, both of the terminals coupled to the ground reference terminal GND and discharges.

[0089] The coupling switch **22** is kept in the ON state only between t_{1a} and t_2 and is OFF when the comparison signal S_{CMP_OFF} assumes a low value. In this way, the intermediate value I_{RES} of the current that supplies the load **20** through the inductor **18** assumes a constant value even as the supply voltage of the load **20** varies, i.e., as T_{OFF} varies. The time interval T_{OFF} during which the inductor **18** is discharged assumes in fact a value that varies according to the value of output voltage V_{OUT}.

[0090] In greater detail, it is found that the value of current $i_{C\_OFF}=i_{OFF\_OUT}$ is equal to $N \cdot V_{OUT}/(R_{OFF})$, where, it is recalled, N is the value of current gain of the current mirror **116** (for example, if N=10 then $i_{C\_OFF}=10V_{OUT}/R_{OFF}$). Consequently, we have that the value of the interval T_{OFF} is equal to $(R_{OFF} \cdot C_{OFF} \cdot S_{REF\_OFF})/(N \cdot V_{OUT})$, where C_{OFF} is the value of capacitance of the capacitor **134**.

[0091] The variation of current ΔI between the maximum value I_{Lmax} and the intermediate value I_{RES} (i.e., $\Delta I=I_{Lmax}-I_{RES}$) is given by $(T_{OFF} \cdot V_{OUT})/L$, where L is the inductance of the inductor **18**. From this it follows that the value of intermediate current I_{RES} is given by $I_{Lmax}-\Delta I$:

$$I_{RES}=(3R_{ON} \cdot C_{ON} \cdot S_{REF\_ON})/(M \cdot L)-(R_{OFF} \cdot C_{OFF} \cdot S_{REF\_OFF})/(N \cdot L)$$

[0092] To return to FIG. **2**, the converter **10** further comprises a first voltage comparator **140** electrically coupled between the inductor **18** and the coupling switch **22** (i.e., electrically connected to the terminal **18***b* of the inductor **18**).

[0093] The first voltage comparator **140** is shown in greater detail in FIG. **7** and comprises a first input terminal, which is connected between the terminal **18***b* of the inductor **18** and the anode of the diode **24**, a second input terminal, which is connected to the cathode of the diode **24** and receives the output voltage V_{OUT}, a third input terminal, which is coupled to the ground reference terminal GND and an output terminal, which is configured to supply a control signal S_{CTR_PT} that identifies whether the step of passive transfer (i.e., transfer obtained by passive components, such as the diode **24**) of energy to the load **20** has terminated or is in progress (step of FIGS. **3**C, **4**C). The first voltage comparator **140** comprises a current-limited inverter **142** formed by a transistor **144**, in particular a MOSFET of a p-channel type and by a transistor **146**, in particular a MOSFET of an n-channel type. The transistor **144** and the transistor **146** have their respective drain terminals connected together and their respective gate terminals connected to the terminal **18***b* of the inductor **18**. Further, the source terminal of the transistor **146** is coupled to the ground reference GND, whereas the source terminal of the transistor **144** is coupled to the cathode of the diode **24** for receiving the output voltage V_{OUT}. The first voltage comparator **140** further comprises a buffer **148**, having an input coupled to the drain terminals of the transistors **144** and **146** and an output configured to supply the control signal S_{CTR_PT}. The buffer **148** has the function of rectifier, for generating at output a signal that is correlated to the signal that it receives at input but has faster rising and falling edges. The buffer **148** is configured to receive at input a signal varying in the range $0-V_{OUT}$ and generate at output a signal having a low logic value "0" if the input is below a predefined threshold, for example equal to $V_{OUT}/2$, or else a high logic value "1" if the input is above the predefined threshold, or vice versa. Preferably, the buffer **148** has a threshold with hysteresis.

[0094] The presence of the current generator **149**, between the inverter **142** and the second input terminal at voltage V_{OUT}, represents a current limitation, for example obtained using a current mirror with p-channel transistors, for limiting the current through the inverter **142** to a value of 100 nA.

[0095] In use, during the steps of active transfer (FIGS. **3**B, **4**B) and passive transfer (FIGS. **3**C, **4**C), the signal present on the gate terminal of the transistors **144** and **146** is such as to drive the transistor **144** into the OFF state and the transistor **146** into the ON state.

[0096] In use, when the coupling switch **22** is OFF and transfer of energy to the load **20** occurs only via the diode **24**, the inductor current I_L drops to the zero value. Also the voltage V_{BE} across the diode **24** drops until it reaches to the zero value. We thus have a zero voltage drop on the diode **24** and the terminal **18***b* is found at an output voltage V_{OUT}. Supply of the load **20** is thus concluded. However, the inductor current I_L continues to drop (i.e., an inverse current is present in the inductor **18**) as a result of the parasitic capacitances that couple the terminal **18***b* of the inductor to the ground reference terminal GND (there should here be considered, in general, all the parasitic capacitances present and deriving from the manufacturing steps, for example from production of the transistors that provide the switches **23** and **58**). The drop in voltage on the terminal **18***b* causes turning-off of the transistor **146** and turning-on of the transistor **144**. Consequently, the control signal S_{CTR_PT} changes its logic state, going from the low logic value "0" to the high logic value "1". The control signal S_{CTR_PT}="1" identifies the end of the step of FIGS. **3**C and **4**C and determines passage to the next step of FIGS. **3**D and **4**D.

[0097] Passage from the step of passive supply of the load **20** to the step of stabilization of the inductor current I_L is obtained by closing the anti-oscillation switch **58**. The converter **10** remains in the step of FIG. **3**D until the inductor current I_L settles to the zero value (i.e., to the reference voltage value GND). FIG. **8** shows a circuit implementation of a second voltage comparator **150** configured to monitor, during the step of FIG. **3**D, the voltage on the node **18***b*, which is proportional to the inductor current I_L. For this purpose, the second voltage comparator **150** is electrically coupled between the terminal **18***b* of the inductor **18** and the anode of the diode **24**, to the ground reference terminal GND and to the supply voltage V_{DD} (supply terminal **80**). The second voltage comparator **150** comprises a current mirror **151**. The current mirror **151** includes a transistor **152**, of an n-channel type, coupled between the terminal **80** at the supply voltage V_{DD} and the ground reference terminal GND and a transistor **153**, of an re-channel type, coupled between the terminal **80** at the supply voltage V_{DD} and the terminal **18***b* of the inductor **18**. The current generators **154**, **155**, set between the transistor **152** and the supply terminal **80** and, respectively, between the transistor **153** and the supply terminal **80**, represent schematically a current limitation and are, for example, implemented by a pair of current mirrors with p-channel transistors, for limiting the current that flows in the respective branches to a value of some hundreds of nanoamps. The second voltage comparator **150** further comprises a buffer **158**, having the function of rectifier, electrically coupled to the drain terminal of the transistor **153**, for collecting the signal that flows in the branch that includes the generator **155** and the transistor **153** and for generating at output a control signal S_{CTR_AR} that is correlated to the signal that it receives at input but has faster rising and falling edges. The buffer **158** is thus configured to receive at input a signal that varies in the range 0-V_{DD} and generating at output a signal having a low logic value "0" if the input is below a predefined threshold (said threshold is equal to $V_{DD}/2$), or else a high logic value "1" if the input is above the predefined threshold. Preferably, the buffer **158** has a threshold with hysteresis.

[0098] According to one embodiment, the current mirror **151** may have a mirror ratio 10:2 in order to speed up the state transitions of the signal set at input to the buffer **158**. However, a current mirror **151** with a different ratio, for example 1:1, may be used.

[0099] In use, when the anti-oscillation switch **58** is ON, an inverse current $-I_L$ flows in the inductor **18** (from the terminal **18***b* to the terminal **18***a*), generating a negative voltage on the terminal **18***b*, equal to $-I_L \cdot R_{AR}$, where R_{AR} is the ON-resistance of the anti-oscillation switch **58**. The output of the buffer **158** assumes a low logic value "0" as long as a negative voltage remains on the terminal **18***b* and then goes to a high logic value "1" when the voltage on the terminal **18***b* reaches the predefined threshold value.

[0100] FIG. **9** shows the first and second driving circuits **25**, **26** connected to the main bridge **12**, according to one embodiment of the present invention.

[0101] With reference to the high-side switch **13**, the first driving circuit **25** coupled thereto is configured to drive the high-side switch **13** alternatively into an open state, in which the high-side switch **13** does not conduct current and into a closed state, in which the high-side switch **13** conducts current. With reference to a high-side switch **13** of a n-channel MOSFET type, the first driving circuit **25** is configured to appropriately bias the gate terminal G of the high-side switch **13** in such a way that, when it is necessary to close the high-side switch **13**, the voltage between the source terminal S and the gate terminal G will be higher than the threshold voltage of turning-on of the high-side switch **13**. For this purpose, the first driving circuit **25** comprises a bootstrap circuit. In detail, the first driving circuit **25** is coupled to: the supply terminal **80**, at a voltage V_{DD}; a recharge switch **30** (in particular, FIG. **9** shows a MOSFET **30'**, of a p type, with integrated diode **30"** having the drain terminal D connected to the supply terminal **80**); and a capacitor **29**, having a capacitance C_{BOOT} comprised between approximately 200 pF and approximately 700 pF, for example approximately 400 pF, connected between the source terminal S of the recharge switch **30** and the terminal **18***a* of the inductor **18**.

[0102] The recharge switch **30** is configured to couple the capacitor **29** to the supply terminal **80** for charging the capacitor **29** by the voltage V_{DD} and, alternatively, to uncouple the capacitor **29** from the supply terminal **80**. The first driving circuit **25** further comprises additional switches **32** and **33**. The switch **32** is connected between the source terminal S and the gate terminal G of the recharge switch **30**, whereas the switch **33** is connected between the gate terminal G of the recharge switch **30** and the ground reference terminal GND.

[0103] The switches **32** and **33** are, for example, MOSFETs driven in conduction and inhibition by a respective control signal ϕ_A and ϕ_B, applied to the gate terminal of the respective switch **32**, **33**. The control signals ϕ_A and ϕ_{dB} are generated by a logic external to the first driving circuit **25** for implementing proper operation of the circuit **25** during the steps described with reference to FIGS. **3**A-**3**D and **4**A-**4**D.

[0104] The high-side switch **13** and the low-side switch **14** have their gate terminals G connected to a respective driving device **34**, **35**. For example, the first and second driving devices **34**, **35** are each formed by a chain of "m" inverters, where "m" is an even number.

[0105] With reference to the driving device **34**, the latter comprises a first supply input **34***a* and a second supply input **34***b*, which are connected to a floating supply, between V_P and V_{BOOT} (where V_P is the voltage on the terminal **18***a* of the inductor **18**), for generating at output a signal V_{HS} configured to drive (open/close) the high-side transistor **13** on the basis of a signal V_{HS}' that it receives at input. Since the driving device **34** is supplied at a voltage comprised between V_P and V_{BOOT}, in use it is able to generate a driving voltage on the gate terminal of the high-side switch **13** higher than the voltage V_P applied to the source terminal S (in particular higher than the threshold voltage of turning-on of the high-side switch **13**); see, for example, in FIG. **10**C, the voltage V_X.

[0106] With reference to the driving device **35**, the latter receives at input a signal V_{LS}' (which is also generated by the control logic) and generates at output a signal V_{LS} configured to drive (open/close) the low-side transistor **14**. Since the low-side transistor **14** has its source terminal S connected to the ground reference GND, it is not necessary to provide a supply circuit similar to the one described with reference to the driving device **34** that will guarantee voltages on the gate terminal G that vary as a function of the voltage assumed by the source terminal S.

[0107] FIG. **10**A shows, as a function of time t (axis of the abscissae), the timing diagram of the signals V_{HS}' and V_{LS}' applied, respectively, to the driving device **34** and **35**. FIG. **10**B shows, using the same time scale as that of FIG. **10**A, the timing diagram of the control signals ϕ_A and ϕ_B, which are configured to drive in opening and closing the switches **32** and **33** of FIG. **9**. FIG. **10**C shows, using the same scale time as that of FIGS. **10**A and **10**B, the plot of the voltage signal V_{BOOT} and of the voltage signal V.

[0108] When the low-side switch **14** is closed (signal V_{LS}' high), the terminal **18***a* is connected to the ground reference voltage GND and the signal V_P is thus at the ground reference voltage GND (e.g., approximately 0 V).

[0109] During this time interval the capacitor **29** is charged by the voltage V_{DD}. This is made possible by connecting the capacitor **29** to the supply terminal **25***a* by closing the switch **30** (the switch **33** is closed and the switch **32** is open). As has already been said, during the time interval in which the low-side switch **14** is closed, the inductor **18** is connected to ground GND and a discharge current flows through the low-side switch **14**.

[0110] When it is necessary the recharge the inductor **18**, the switch **30** is opened (by opening the switch **33** and closing the switch **32**). Preferably, the low-side switch **14** is opened prior to closing of the high-side switch **13** in order to prevent phenomena of cross conduction. The capacitor **29**, which had previously been charged, maintains the charge stored and supplies the driving device **34**, which, in turn, biases the control terminal of the high-side switch **13**, driving it into conduction. The supply terminal **12***a* is thus connected to the terminal **18***a* of the inductor **18**, enabling supply of the electrical load as explained previously.

[0111] From FIGS. **10**A and **10**B it may be noted that the signal V_{LS}' is at a high value when the control signal ϕ_A is at a high value (switch **32** open) and the signal V_{HS}' is at a low value. During this interval, the capacitor **29** is recharged. When the signal V_{LS}' drops, also the control signal ϕ_A drops (closing the switch **32**). At the same time, the control signal ϕ_B rises (opening the switch **33**). After a certain time interval, also the signal V_{HS}' rises. Between the falling edge of the signal V_{LS}' and the rising edge of the signal V_{HS}' a dead time is in fact envisaged to prevent phenomena of cross conduction.

[0112] With closing of the high-side switch **13** the voltage V_P rises to the value V_{IN}.

[0113] In this step, in which the switch **33** is open and the switch **32** is closed, the capacitor **29** is in a charged condition ($V_{BOOT} \approx V_{DD}$). With turning-on of the high-side switch **13**, the node at V_P rises in voltage and, as a result of the (capacitive) bootstrap, also the voltage on the opposite plate of the capacitor **29** (bootstrap capacitor) rises. The voltage V_X across the capacitor **29** is kept substantially constant (but for minor losses). In this way, during the step of turning-on of the high-side switch **13**, the driving device **34** is supplied and is thus able to turn on the high-side switch **13**.

[0114] The voltage drop V_X across the capacitor **29** when the high-side switch **13** is closed is given by

$$V_X = V_{DD}\left(1 - \frac{C_{GS}}{C_{BOOT} + C_{GS}}\right)$$

[0115] where C_{GS} is the capacitance between the gate terminal and the source terminal of the high-side transistor **13**.

[0116] The embodiment of FIG. **9** enables minimization of the area required for the ensemble formed by the high-side switch **13** and the first driving circuit **25**, maintaining good characteristics of performance as regards the ON-resistance (R_{ON}) and enabling a complete integration of the first driving circuit **25** and of the high-side switch **13** without the need to use external components.

[0117] To return to FIG. **2**, the converter **10** further comprises, according to one embodiment, a hysteretic comparator **87** (of a per se known type, in which the hysteresis is defined between a first threshold V_{th}^- and a second threshold V_{th}^+, with $V_{th}^- < V_{th}^+$). The hysteretic comparator **87** comprises an inverting input configured to receive the output signal V_{OUT} and a non-inverting input configured to receive a reference signal V_{ref_c}.

[0118] The reference signal V_{ref_c} is a bandgap reference, independent of the supply voltage and of the temperature.

[0119] The output of the hysteretic comparator **87** indicates the level of voltage assumed by the output signal V_{OUT}. The signal V_{comp} generated at output by the hysteretic comparator **87** is used during the steps of supply of the electrical load **20** for detecting whether the electrical load **20** needs to be supplied or not. The electrical load **20**, in fact, is supplied (recharged) only when necessary, i.e., when the output voltage signal V_{OUT} drops below the threshold defined by the reference signal V_{ref_c}.

[0120] The hysteretic comparator **87** has two possible output logic levels, in particular the ground reference value GND (or equivalent) and the value of the supply signal (V_{DD}). When the output signal V_{comp} of the hysteretic comparator **87** is equal to V_{DD}, then the output voltage V_{OUT} has dropped below the reference V_{ref_c} and the respective electrical load **20** must be supplied. When the output signal V_{comp} of the hysteretic comparator **87** is equal to the ground reference GND, then the output voltage V_{OUT} is higher than the reference V_{ref_c} and the electrical load **20** does not have be supplied. The characteristic of the comparator **87** is centered around the reference V_{ref_c} and is the classic hysteretic characteristic (indicatively with thresholds $V_{th}^+ > V_{ref\_c}$ and $V_{th}^- < V_{ref\_c}$).

[0121] In order to decide whether the electrical load **20** needs to be supplied, the output signal V_{OUT} is monitored in a continuous way or at regular intervals. If the output signal V_{OUT} drops below the threshold V_{th}^- of the hysteretic comparator **87**, the electrical load **20** is supplied and charged. The charging step is not carried out if the output signal V_{OUT} exceeds the threshold V_{th}^+. Each comparator **87** is configured to have the hysteresis equal to the maximum value of ripple tolerated by the specific application, for example approximately 10-50 mV.

[0122] In order to manage the operating steps of the converter **10**, i.e., the steps described with reference to FIGS. **3**A-**3**D and **4**A-**4**D, for passage from one step to the next and for verifying whether the electrical load **20** needs to be supplied or not, the converter **10** further comprises a control logic **85**, for example an integrated digital controller, as shown schematically in FIG. **11**. The control logic **85** carries out generation of the signals to turn-on/turn-off the high-side switch **13** and the low-side switch **14** and generation of the control signals of the switches **57** (FIG. **5**) and **103** (FIG. **6**), of the anti-oscillation switch **58**, of the switch **23** and of the enable signals S_{EN_ON} and S_{EN_OFF} in order to implement the operating steps described previously.

[0123] In greater detail, the control logic **85** implements the steps of the method for operating the converter **10** according to FIG. **12**, functioning as a state machine.

[0124] With joint reference to FIGS. **11** and **12**, during an initial step (step S**1**), the control logic **85** verifies in the first place whether the electrical load **20** needs to be supplied. In this step, the low-side switch **14** and the charge switch **23** are ON, whereas all the other switches are OFF.

[0125] The above verification step is carried out, as has been said, on the basis of the value assumed by the signal V_{comp} generated by the comparator **87**. If the electrical load **20** does not have to be supplied (output NO from step S**1**), the logic returns into the mode of observation of the signal V_{comp} and waits for the electrical load **20** to require charging. Otherwise, if the electrical load **20** is to be supplied (output YES from step S**1**) control passes to step S**2**.

[0126] In the case where the electrical load **20** does not need to be supplied, the remaining steps of FIG. **12** are not carried out. In this case, it is further envisaged that the control logic **85** will send a signal for selective turning-off of portions of the converter **10** so that a further energy saving will be guaranteed and thus an increase of efficiency of the converter itself. In detail, the control logic electrically uncouples the adaptive control blocks **51** and **101** by closing (turning off) the switches **57** shown in FIGS. **5** and **103** shown in FIG. **6**.

[0127] In this initial resting step, the high-side switch **13**, as likewise the coupling switch **22** and the anti-oscillation switch **58**, are open (i.e., in the case of a MOSFET, OFF). Only the low-side switch **14** and the charge switch **23** are ON, thus connecting both of the terminals of the inductor **18** to the reference terminal GND.

[0128] Passage to the subsequent steps, however, determines closing of the switches **57** and **103** so that the adaptive-control blocks **51** and **101** are supplied and immediately available for operation.

[0129] In step S**2**, the control logic **85** opens the low-side switch **14** (by the signal V_{LS}) and then closes the high-side switch **13** (i.e., it turns on the transistor **13** by the signal V_{HS}). This operation is carried out by generating the signals ϕ_A and ϕ_B of FIG. **9** to close the switch **32** and open the switch **33**. The signals ϕ_A and ϕ_B generated by the control logic **85** are voltage signals that have an amplitude appropriate for controlling the switches **32** and **33** (for example, in the case of switches **32**, **33** of a MOSFET type, the voltage signals generated by the driving devices as a function of the signals ϕ_A and ϕ_B are such as to drive the respective MOSFETs into conduction by generating a gate-to-source voltage higher than the threshold voltage of the respective MOSFET).

[0130] As described previously, following upon generation of the signals Φ_A and Φ_B, the signal V_{HS}' that enables closing of the high-side switch **13** via the driving device **34** is asserted. Likewise, together with the high-side switch **13**, also the charge switch **23** remains closed by the control logic **85**, by the signal Φ_c. The terminal **18***b* is thus coupled to the ground reference terminal GND. A current may thus start to flow through the inductor **18**, from the terminal **12***a* to the terminal GND.

[0131] As soon as the high-side switch **13** conducts, the voltage on the terminal **18***a* starts to rise, locking to the value V_{IN}. At the same time, owing to the capacitive effect, since the difference of potential across the capacitor **29** remains unvaried, the voltage V_{BOOT} rises, enabling the driving device **34** to generate a signal V_{HS} such as to keep the high-side switch **13** in conduction. The inductor **18** may thus be charged.

[0132] As shown in step S**3**, which is temporally simultaneous to step S**2**, or immediately subsequent to step S**2**, monitoring of the time interval T_{ON} starts by activating the first adaptive control block **51**. For this purpose, the enable signal S_{EN_ON} assumes a low logic value "0", such as to drive the transistor **76** of FIG. **5** into conduction, thus charging the capacitor **84**.

[0133] The control logic **85** (step S**4**) immediately starts monitoring of the comparison signal S_{CMP_ON} generated at output by the adaptive control block **51**. During the interval T_{ON}, the comparison signal S_{CMP_ON} has a high logic value "1"; passage of the value of the comparison signal S_{CMP_ON} to a low logic value "0" is interpreted by the control logic **85** as the end of the interval T_{ON}. As long as the comparison signal S_{CMP_ON} has a high logic value "1" (output NO from step S**4**), the control logic **85** remains in step S**4** (i.e., in the condition of FIGS. **3**A, **4**A). Otherwise (output YES from step S**4**), control passes to step S**5**.

[0134] Entry into step S**5** determines transition from the operating condition of FIGS. **3**A, **4**A to the operating condition of FIGS. **3**B, **4**B.

[0135] In step S**5**, the high-side switch **13** is opened (the control logic **85** generates an appropriate signal V_{HS}' such that, via the driving device **34**, the high-side switch **13** is driven into the open state—transistor **13** OFF). Instead, the low-side switch **14** is closed (transistor **14** ON). Preferably, the control logic introduces a delay (dead time) between opening of the high-side switch **13** and closing of the low-side switch **14**.

[0136] The low-side switch **14** is driven into the closed state by generating the signal V_{LS}', which is applied, via the driving device **35**, to the control terminal of the low-side switch **14**. The signals V_{LS}' and V_{HS}' are, for example, CMOS logic signals of amplitude equal to V_{DD}.

[0137] Simultaneously with opening of the high-side switch **13** and, preferably, prior to closing of the low-side switch **14**, the charge switch **23** is opened, thus uncoupling the terminal **18***b* from the ground reference GND.

[0138] The control logic **85** further generates, following upon (or simultaneously with) closing of the low-side switch **14**, a signal Φ_{out} for driving the coupling switch **22** (possibly via a buffer **160** for matching the voltage level of the signal Φ_{out} to the voltage level accepted at input by the gate terminal of the transistor that constitutes the coupling switch **22**). The signal Φ_{out} drives the coupling switch **22** into conduction, thus connecting the inductor **18** to the electrical load **20**. The inductor **18** is thus discharged in the active mode.

[0139] During step S**5** of discharge of the inductor **18**, the time interval T_{OFF} is monitored by the control logic **85** by operating the second adaptive control block **101**. For this purpose (step S**6**), simultaneously with (or immediately after) closing of the switch **22**, the control logic **85** sets the signal S_{EN_OFF} to the low logic value "0", thus turning on the transistor **126** and charging the capacitor **134**.

[0140] The control logic **85** monitors (step S**7**) constantly, or at regular intervals, the value of the comparison signal S_{CMP_OFF} generated at output by the adaptive control block **101** in order to identify the end of the interval T_{OFF}. A high logic value "1" of the comparison signal S_{CMP_OFF} (output NO from step S**7**) maintains the control logic **85** in a wait state. The variation of the comparison signal S_{CMP_OFF} from the high logic value "1" to the low logic value "0" (output YES from step S**7**) determines the end of the interval T_{OFF} and passage from the operating condition of FIGS. **3**B, **4**B to that of FIGS. **3**C, **4**C (passive supply of the load **20**). This passage corresponds to the transition from step S**7** to step S**8**.

[0141] In step S**8**, the control logic **85** sets the enable signal S_{EN_OFF} to the high logic value "1", thus discharging the capacitor **134**. Active supply of the load **20** is concluded and consequently the control logic **85** turns off the coupling switch **22** by the signal Φ_{out}.

[0142] Control then passes to step S**9**, in which the control logic **85** monitors the value of the control signal S_{CTR_PT}: as long as the logic value of the control signal S_{CTR_PT} is low, "0", the control logic **85** remains in step S**9**. Instead, when the logic value of the control signal S_{CTR_PT} passes to the high value "1" (output YES from step S**9**), then the control logic **85** drives the anti-oscillation switch **58** into the closed state (step S**10**) by generating an appropriate signal Φ_a. This step corresponds to the operating condition of FIGS. **3**D, **4**D.

[0143] After step S**10**, the control logic **85** goes immediately to the next step S**11**, where the control signal S_{CTR_AR} generated by the block **150** is acquired and monitored. Transition of the logic state of the control signal S_{CTR_AR}, as already described with reference to FIG. **8**, determines the end of step S**11**. The operating condition of FIGS. **3**D, **4**D terminates with opening of the anti-oscillation switch **58**. The steps of supply of the load **20** have terminated and the control logic **85** returns to step S**1**, activating the charge switch **23** and the low-side switch **14** to maintain the terminals **18***a* and **18***b* of the inductor **18** at the reference terminal GND.

[0144] Steps S**2**-S**12** are, for example, managed on the basis of a timing supplied by a clock signal (CLK) generated outside the circuit converter **10** or generated by a clock circuit of an integrated type. The clock frequency CLK is, for example comprised between approximately 100 kHz and approximately 400 kHz, for example approximately 230 kHz. The clock signal CLK may be generated by an oscillator circuit of a known type. On each rising edge of the clock signal a time slot is generated for the respective step of supply of the load **20**, having a duration equal to the period of oscillation of the clock signal. When the output does not need to be recharged, the clock is set in sleep, i.e., low-consumption, mode and so the time slot is generated. As soon as the output needs to be charged (as determined by step **S1**), the state machine wakes up and restarts with generation of the time slots for supplying the electrical loads that need to be supplied.

[0145] It is evident that use of a clock signal CLK is not necessary and may be omitted. In this case, the control logic starts the operations of steps **S1**-**S12** immediately according to the need and the entire sequence is carried out without a timing supplied by a clock.

[0146] FIG. **13** shows an energy harvesting system **200** comprising the converter **10**. The energy harvesting system **200** is similar to the energy harvesting system **1** of FIG. **1** (elements that are in common are designated by the same reference numbers) and is not described any further herein.

[0147] The transducer **2** may be chosen in the group comprising: electrochemical transducers (configured to convert chemical energy into an electrical signal), electromechanical transducers (configured to convert mechanical energy into an electrical signal), electroacoustic transducers (configured to convert variations of pressure into an electrical signal), electromagnetic transducers (configured to convert a magnetic field into an electrical signal), photoelectric transducers (configured to convert light energy into an electrical signal), electrostatic transducers and thermoelectric transducers.

[0148] The converter **10** is connected to the output of the scavenging interface **4**. The energy stored in the storage capacitor of the scavenging interface **4** (which is of a per se known type) supplies the converter **10**. The input voltage of the converter **10** is thus the voltage produced by the scavenging interface **4**.

[0149] According to one application of the energy harvesting system **200**, generation of electrical energy exploits the mechanical energy produced by an individual when he is walking or running. In this case, the energy harvesting system **200** is set inside the shoes of the individual in question (for example, inside the sole). In systems aimed at fitness, where counting of the steps is of particular interest, it is useful to harvest energy from the vibrations induced by walking/running to be able to supply without the use of a battery acceleration sensors and/or wireless transmitters (for example, RFID, BT, etc.), which are able to communicate with cellphones, music-player devices, or with any other apparatus concerned with providing information on the steps performed.

[0150] A further application of the energy harvesting system **200** envisages harvesting the thermal energy supplied by a source of thermal energy, e.g., through a thermoelectric transducer.

[0151] From an examination of the characteristics of the invention obtained according to the present disclosure the advantages that it affords are evident.

[0152] In particular, the converter **10** according to the present invention enables electrical supply of loads that require low supply voltages, with high efficiency using a single inductor **18**.

[0153] Further, the converter **10** may be completely integrated in an energy harvesting system **200**, which must typically guarantee a high level of performance and resistance in regard to stresses. The high integratability is enabled by the presence of the bootstrap network to turn on the high-side switch, which is of a type set inside (integrated in) the converter **10**.

[0154] Further, the adaptive control circuit **51** enables the converter **10** to be operated in a constant-peak-current mode over a wide range of input voltages, enabling compensation of the time interval T_{ON} for different values of the input voltage V_{IN}. Likewise, the adaptive control circuit **101**, together with the control logic of the coupling switch **22**, enables supply of the electrical load in a precise way, discharging the inductor completely at each step of supply of the load **20**, without absorbing current from the load **20** itself and using, during the final discharging step, passive elements, thus minimizing the consumption of current by the converter **10**.

[0155] Finally, it is clear that modifications and variations may be made to what has been described and illustrated herein, without thereby departing from the scope of the present invention, as defined in the annexed claims.

[0156] In particular, according to a different embodiment (not described in detail), the converter **10** may be of a SIMO (single-inductor multiple-output) type, having a plurality of outputs configured to supply a respective plurality of electrical loads. In this case, a respective plurality of coupling switches **22** is present, each of which is configured to couple the terminal **18*b*** of the inductor **18** with a respective electrical load. For supplying the plurality of electrical loads it is possible to use, for example, a time-multiplexing technique, for example of the type described in the patent application No. EP 2518878.

[0157] Further, the present invention is irrespective of the circuit architecture of the DC-DC converter. It may be applied to any DC-DC converter of a SIMO or SISO type, for example of a buck type, of a boost type, or else of a buck-boost type.

[0158] Only in the case of a DC-DC converter of a buck type does the operating condition of charging (interval T_{ON}) have a duration calculated as a function of the value assumed by the input supply signal V_{IN} minus the output signal V_{OUT}.

[0159] Likewise, only in the case of a DC-DC converter of a boost type does the time interval of active discharge of the inductor (interval T_{OFF}) have a duration $t_{1a}-t_2$ calculated as a function of the value assumed by the output supply signal V_{OUT} minus the input signal V_{IN}.

What is claimed is:

1. A method for operating a converter including an inductor receiving an input supply signal and supplying an electrical load with an output supply signal, the method comprising:

charging the inductor by storing electrical charge until a maximum pre-set current value is reached, during a first operating condition in which said electrical load is not supplied;

actively supplying said electrical load by the electrical charge stored in the inductor during a first time interval of a second operating condition by partially discharging the inductor until an intermediate value of residual charge stored in the inductor is reached; and

passively supplying said electrical load by said residual charge stored in the inductor during a second time interval, subsequent to the first time interval, of the second operating condition.

2. The method according to claim **1**, wherein said first operating condition has a duration calculated as a function of the value assumed by the input supply signal.

3. The method according to claim **1**, wherein the first time interval of the second operating condition has a duration calculated as a function of the value assumed by the output supply signal.

4. The method according to claim **1**, wherein the converter further comprises a charge-transfer switch and a charge-transfer diode coupled together in series between the inductor and the electrical load, the charge-transfer switch being configured to operate in an active operating state, in which the charge-transfer switch is closed and the electrical load is supplied through the charge-transfer switch and in a passive operating state, in which the charge-transfer switch is open and the electrical load is supplied through the charge-transfer diode, wherein actively supplying includes driving the charge-transfer switch into the active operating state and said step of passive supply of said electrical load including driving the charge-transfer switch into the passive operating state.

5. The method according to claim **1**, wherein the converter further comprises a first adaptive control circuit including a first electrical-charge-storage device and a first signal comparator and a second adaptive control circuit including a second electrical-charge-storage device and a second signal comparator, the method further comprising:

charging the first electrical-charge-storage device, during the first operating condition, by a first charging signal correlated to the input supply signal;

generating, by the first signal comparator, a first control signal when the charge stored in the first electrical-charge-storage device reaches a first predefined threshold;

charging the second electrical-charge-storage device, during the second operating condition, by a second charging signal correlated to the output supply signal;

generating, by the second signal comparator, a second control signal when the charge stored in the second electrical-charge-storage device reaches a second predefined threshold, wherein said first predefined threshold indicates a maximum value that the electrical charge stored in said inductor may assume during the first operating condition and the second predefined threshold indicates the intermediate value that the electrical charge stored in said inductor may assume during the second operating condition.

6. The method according to claim **5**, wherein the converter further comprises a charge switch and a discharge switch, coupled in series to one another between a source of electrical energy that supplies the input supply signal and a reference terminal, said inductor having a first conduction terminal and a second conduction terminal, the first conduction terminal being electrically coupled between the charge switch and the discharge switch and the second conduction terminal being electrically coupled to the ground reference terminal via a coupling switch,

the method further comprising:

turning on the charge switch, by turning on the coupling switch and turning off the discharge switch, in order to charge the inductor during the first operating condition;

passing from the first operating condition to the second operating condition upon reception of the first control signal, by turning off the charge switch and the coupling switch, by turning on the discharge switch and by driving the charge-transfer switch into the active operating state; and

driving a transition from the active operating state to the passive operating state of the charge-transfer switch upon reception of the second control signal.

7. A converter for supplying an electrical load by an output supply signal, comprising:

an input stage operatively coupled between a source of electrical energy configured to supply an input supply signal and a reference terminal;

an inductor having a first conduction terminal and a second conduction terminal, the first conduction terminal being electrically coupled to the input stage and the second conduction terminal being selectively electrically coupled to the ground reference terminal; and

a charge-transfer switch and a charge-transfer diode coupled in series to one another between the second conduction terminal of the inductor and an electrical load, the charge-transfer switch being configured to electrically uncouple the second conduction terminal from the electrical load during a first operating condition in which the inductor is charged by the input supply signal and electrically couple the second conduction terminal to the electrical load during a second operating condition in which the electrical load is supplied,

wherein the charge-transfer switch is configured to operate in an active operating state in which the charge-transfer switch is closed and the electrical load is supplied through the charge-transfer switch and in a passive operating state in which the charge-transfer switch is open and the electrical load is supplied through the charge-transfer diode.

8. The converter of claim **7**, further comprising:

a first adaptive control circuit including a first electrical-charge-storage device operatively coupled to the source of electrical energy and a first signal comparator, wherein the first electrical-charge-storage device is configured to be charged, during the first operating condition, by a first charging signal correlated to the input supply signal and the first signal comparator is configured to generate a first control signal when the charge stored in the first electrical-charge-storage device reaches a first predefined threshold; and

a second adaptive control circuit including a second electrical-charge-storage device operatively coupled to the electrical load and a second signal comparator, wherein the second electrical-charge-storage device is configured to be charged, during the second operating condition, by a second charging signal correlated to the output supply signal and the second signal comparator is configured to generate a second control signal when the charge stored in the second electrical-charge-storage device reaches a second predefined threshold,

wherein said first predefined threshold indicates a maximum value that the electrical charge stored in said inductor may assume during the first operating condition and the second predefined threshold indicates an intermediate value, comprised between a zero value and said maximum value, that the electrical charge stored in said inductor may assume during the second operating condition.

9. The converter of claim **7**, further comprising a control logic configured to:

control the input stage for coupling, during the first operating condition, the inductor to the source of electrical energy thus charging the inductor;

pass from the first operating condition to the second operating condition upon reception of the first control signal by driving the input stage for uncoupling the inductor from the source of electrical energy and driving the charge-transfer switch into the active operating state; and

drive a transition from the active operating state to the passive operating state of the charge-transfer switch upon reception of the second control signal.

10. The converter according to claim **7**, wherein said charge-transfer switch is a transistor having an integrated diode, said active operating state corresponding to a flow of electrical charge through the channel of said transistor obtained by turning on the transistor and said passive operating state corresponding to a flow of electrical charge through the integrated diode when the transistor is OFF.

11. The converter according to claim **8**, wherein said first adaptive control circuit further comprises:

a first voltage-to-current converter, electrically coupled to the source of electrical energy for receiving the input supply signal and configured to generate a first intermediate current signal correlated to the input supply signal; and

a first amplifier, configured to receive the first intermediate current signal and generating said first charging signal by amplifying the first intermediate current signal.

12. The converter according to claim **11**, wherein said first adaptive control circuit further comprises a first enabling switch configured to receive the first charging signal and supply the first charging signal to said first electrical-charge-storage device and a second enabling switch configured to couple the first electrical-charge-storage device to a ground reference terminal, and

control logic being configured to:

turn on said first enabling switch and turning off said second enabling switch, during the first operating condition, thus charging the first electrical-charge-storage device; and

turn off said first enabling switch and turning on said second enabling switch, outside the first operating condition, thus discharging the first electrical-charge-storage device.

13. The converter according to claim **8**, wherein said second adaptive control circuit further comprises:

a second voltage-to-current converter configured to receive the output supply signal and configured to generate a second intermediate current signal correlated to the output supply signal; and

a second amplifier configured to receive the second intermediate current signal and generating said second charging signal by amplifying the second intermediate current signal.

14. The converter according to claim **13**, wherein said second adaptive control circuit further comprises a third enabling switch configured to receive the second charging signal and supply the second charging signal to said second electrical-charge-storage device and a fourth enabling switch configured to couple the second electrical-charge-storage device to a ground reference terminal, and

control logic configured to:

turn on said third enabling switch and turning off said fourth enabling switch, during the second operating condition, thus charging the second electrical-charge-storage device; and

turn off said third enabling switch and turning on said fourth enabling switch, outside of the second operating condition, thus discharging the second electrical-charge-storage device.

15. The converter according to claim **7**, further comprising an output comparator configured to acquire said output supply signal and comparing the output supply signal alternatively with a lower supply-threshold value and with an upper supply-threshold value to generate an output comparison signal, and

control logic configured to acquire the output comparison signal and turn off the converter if the output supply signal reaches the upper supply-threshold value and, alternatively, re-activating the converter, by coupling the inductor to the source of electrical energy, if the output supply signal reaches the lower supply-threshold value.

16. The converter according to claim **7**, further comprising:

a monitoring circuit configured to monitor the electrical charge transferred through the charge-transfer switch during the passive operating state of the charge-transfer switch and to generate a monitoring signal indicating a substantially zero transfer of electrical charge to the electrical load;

an anti-oscillation switch connected between the second terminal of the inductor and the ground reference terminal, and

control logic configured to turn on the discharge switch and the anti-oscillation switch upon reception of the monitoring signal.

17. The converter according to claim **7**, wherein the input stage comprises a charge switch and a discharge switch connected together in series, the charge switch being coupled to the source of electrical energy and the discharge switch being coupled to the reference terminal, and

wherein the first conduction terminal of the inductor is electrically coupled between the charge switch and the discharge switch and the second conduction terminal is electrically coupled to the ground reference terminal via a coupling switch.

18. An energy harvesting system configured to supply at least one electrical load (**20**), comprising:

a transducer configured to convert energy coming from an energy source external to said system into an AC/DC electrical signal;

a rectifier circuit configured to receive at input the AC/DC electrical signal generated by the transducer and supplying at output a DC output signal;

a first storage element coupled to the rectifier circuit for receiving at input the DC output signal and configured to store electrical energy; and

a converter according to claim **7** connected between the rectifier circuit and the electrical load and configured to receive at input the DC output signal generated by the rectifier circuit and supply the electrical load.

19. A converter, comprising:

an inductor configured to receive an input supply signal and supply an electrical load with an output supply signal;

a switching circuit coupled to said inductor; and

a control circuit configured to control operation of the switching circuit to:

charge the inductor by storing electrical charge until a maximum pre-set current value is reached during a first operating condition in which said electrical load is not supplied;

actively supply said electrical load by the electrical charge stored in the inductor during a first time interval of a second operating condition that partially discharges the inductor to an intermediate value of residual charge; and

passively supply said electrical load by said residual charge stored in the inductor during a second time interval, subsequent to the first time interval, of the second operating condition.

20. The converter according to claim **19**, wherein the switching circuit comprises:

a charge-transfer switch and a charge-transfer diode coupled between the inductor and the electrical load,

wherein the control circuit closes the charge-transfer switch during active supply of electrical charge to the load, and opens the charge-transfer switch during passive supply of electrical charge to the load, wherein said passive supply is made through the charge-transfer diode.

21. The converter according to claim **19**, further comprising:

a first adaptive control circuit including a first electrical-charge-storage device and a first signal comparator; and

a second adaptive control circuit including a second electrical-charge-storage device and a second signal comparator;

wherein the first electrical-charge-storage device is charged during the first operating condition by a first charging signal correlated to the input supply signal, said the first signal comparator generating a first control signal when the charge stored in the first electrical-charge-storage device reaches a first predefined threshold; and

wherein the second electrical-charge-storage device is charged during the second operating condition by a second charging signal correlated to the output supply signal, said second signal comparator generating a second control signal when the charge stored in the second electrical-charge-storage device reaches a second predefined threshold.

22. The converter according to claim **21**, wherein said first predefined threshold indicates a maximum value that the electrical charge stored in said inductor may assume during the first operating condition and the second predefined threshold indicates the intermediate value that the electrical charge stored in said inductor may assume during the second operating condition.

23. The converter according to claim **21**, wherein the switching circuit comprises:

a charge switch;

a discharge switch;

wherein the charge and discharge switches are coupled in series to one another between a source of electrical energy that supplies the input supply signal and a reference terminal; and

a coupling switch;

wherein said inductor has a first conduction terminal and a second conduction terminal, the first conduction terminal being electrically coupled between the charge switch and the discharge switch and the second conduction terminal being electrically coupled to the ground reference terminal via said coupling switch.

24. The converter according to claim **23**, wherein the control circuit is configured to:

turn on the charge switch, turn on the coupling switch and turn off the discharge switch in order to charge the inductor during the first operating condition;

turn off the charge switch, turn off the coupling switch and turn on the discharge switch during the first time interval of the second operating condition in response to a first control signal; and

turn off the discharge switch during the second time interval of the second operating condition.

(57) ABSTRACT

A method and apparatus is disclosed herein for harvesting ambient energy. In one embodiment, an energy harvester comprises: a first RF rectifier to output a first voltage determined by rectified RF energy in response to received RF energy; a first energy reservoir coupled to the first RF rectifier to store energy at the first voltage; a DC/DC converter coupled to the first energy reservoir to convert the first voltage to a second voltage; a second reservoir coupled to the DC/DC converter to store energy at the second voltage, the second voltage being greater than the first voltage; and a third reservoir coupled to the second reservoir to receive energy transferred from the second reservoir periodically.

SYSTEM FOR AMBIENT ENERGY HARVESTING

FIELD OF THE INVENTION

[0001] Embodiments of the present invention relate to the field of wireless power transfer; more particularly, embodiments of the present invention relate to radio-frequency (RF) energy harvesting devices that harvest ambient RF energy and store the received RF energy.

BACKGROUND OF THE INVENTION

[0002] Next generation sensor networks may be powered by energy harvesting techniques to avoid requiring battery maintenance. Energy harvesting is a process by which energy is derived from external sources (e.g., radio frequency energy, solar power, thermal energy, wind energy, salinity gradients, or kinetic energy), captured and stored.

[0003] Energy may be harvested from radio frequency signals propagating wirelessly. With RF harvesting, wireless energy comes from a radio frequency transmitting device that is some distance away from a device that harvests energy from the radio frequency transmission. Properties of an energy harvester include its ability to harvest energy efficiently from available RF signals, its ability to store the harvested energy efficiently with minimal storage loss, and its ability to make the stored energy available to meet the voltage, current, and duty cycle requirements of a desired application.

[0004] One of the more popular forms of RF used today is Wi-Fi (also referred to as IEEE 802.11a/b/g/n etc.) communications. Today, most Wi-Fi communications are in the 2.4 GHz and 5.8 GHz frequency bands and there are many local area networks that are based on Wi-Fi in which access points enable Wi-Fi clients to gain access to networks such as the Internet. Furthermore, the 2.4 GHz and 5.8 GHz bands also support other networking standards, such as Zigbee and Bluetooth, and other proprietary networks, each transmitting energy by communicating in this same frequency band. Additionally there are other frequency bands that support different communication protocols, each of which transmit energy when they are communicating. These include, for example, digital television (DTV) and Global System for Mobile Communications (GSM) signals.

[0005] In a traditional RFID-like setup the RFID readers (interrogators) usually deliver RF power as a continuous wave (CW), i.e. a sinusoidal signal of a particular frequency. In contrast to systems designed for use with continuous wave (CW) signals such as RFID, some RF energy harvesters are designed for use with non-CW signals such as WiFi and GSM. These waveform aware harvesters include ambient energy harvesters that harvest signals of opportunity that are already present in the environment. For these types of harvesters, the system designer must work around the waveforms and power levels that are already present in the environment.

SUMMARY OF THE INVENTION

[0006] A method and apparatus is disclosed herein for harvesting ambient energy. In one embodiment, an energy harvester comprises: a first RF rectifier to output a first voltage determined by rectified RF energy in response to received RF energy; a first energy reservoir coupled to the first RF rectifier to store energy at the first voltage; a DC/DC converter coupled to the first energy reservoir to convert the first voltage to a second voltage; a second reservoir coupled to the DC/DC converter to store energy at the second voltage, the second voltage being greater than the first voltage; and a third reservoir coupled to the second reservoir to receive energy transferred from the second reservoir periodically.

BRIEF DESCRIPTION OF THE DRAWINGS

[0007] The present invention will be understood more fully from the detailed description given below and from the accompanying drawings of various embodiments of the invention, which, however, should not be taken to limit the invention to the specific embodiments, but are for explanation and understanding only.

[0008] FIG. **1** is a block diagram of one embodiment of a sensor device.

[0009] FIG. **2** is a block diagram of one embodiment of an RF energy harvester.

[0010] FIG. **3** is another more detailed block diagram of one embodiment of an RF energy harvester.

[0011] FIG. **4** illustrates a diode-based rectifier schematic.

[0012] FIG. **5** illustrates a diode output circuit model.

[0013] FIG. **6**A illustrates the usable energy stored in capacitor C_X during one transmission burse of duration T_p.

[0014] FIG. **6**B illustrates examples of good and bad choices of C_X.

[0015] FIG. **7** illustrates one embodiment of a self-excited oscillator.

[0016] FIG. **8** illustrates one embodiment of a charger schematic.

DETAILED DESCRIPTION OF THE PRESENT INVENTION

[0017] A system for ambient energy harvesting and method for doing the same are described. In one embodiment, the energy harvesting system includes three DC reservoirs to store energy generated from ambient radio frequency (RF) input signals. These reservoirs are coupled together in a cascaded fashion to provide DC energy to a load.

[0018] In one embodiment, the ambient RF energy harvester is part of a sensor/tag device and is used to provide energy to one or more components of the sensor/tag device such as, for example, the sensor, a controller, a communication unit a processing device, etc.

[0019] In the following description, numerous details are set forth to provide a more thorough explanation of the present invention. It will be apparent, however, to one skilled in the art, that the present invention may be practiced without these specific details. In other instances, well-known structures and devices are shown in block diagram form, rather than in detail, in order to avoid obscuring the present invention.

[0020] Some portions of the detailed descriptions which follow are presented in terms of algorithms and symbolic representations of operations on data bits within a computer memory. These algorithmic descriptions and representations are the means used by those skilled in the data processing arts to most effectively convey the substance of their work to others skilled in the art. An algorithm is here, and generally, conceived to be a self-consistent sequence of steps leading to a desired result. The steps are those requiring physical manipulations of physical quantities. Usually, though not necessarily, these quantities take the form of electrical or magnetic signals capable of being stored, transferred, combined, compared, and otherwise manipulated. It has proven convenient at times, principally for reasons of common usage, to refer to these signals as bits, values, elements, symbols, characters, terms, numbers, or the like.

[0021] It should be borne in mind, however, that all of these and similar terms are to be associated with the appropriate physical quantities and are merely convenient labels applied to these quantities. Unless specifically stated otherwise as apparent from the following discussion, it is appreciated that throughout the description, discussions utilizing terms such as "processing" or "computing" or "calculating" or "determining" or "displaying" or the like, refer to the action and processes of a computer system, or similar electronic computing device, that manipulates and transforms data represented as physical (electronic) quantities within the computer system's registers and memories into other data similarly represented as physical quantities within the computer system memories or registers or other such information storage, transmission or display devices.

[0022] The present invention also relates to apparatus for performing the operations herein. This apparatus may be specially constructed for the required purposes, or it may comprise a general purpose computer selectively activated or reconfigured by a computer program stored in the computer. Such a computer program may be stored in a computer readable storage medium, such as, but is not limited to, any type of disk including floppy disks, optical disks, CD-ROMs, and magnetic-optical disks, read-only memories (ROMs), random access memories (RAMs), EPROMs, EEPROMs, magnetic or optical cards, or any type of media suitable for storing electronic instructions, and each coupled to a computer system bus.

[0023] The algorithms and displays presented herein are not inherently related to any particular computer or other apparatus. Various general purpose systems may be used with programs in accordance with the teachings herein, or it may prove convenient to construct more specialized apparatus to perform the required method steps. The required structure for a variety of these systems will appear from the description below. In addition, the present invention is not described with reference to any particular programming language. It will be appreciated that a variety of programming languages may be used to implement the teachings of the invention as described herein.

[0024] A machine-readable medium includes any mechanism for storing or transmitting information in a form readable by a machine (e.g., a computer). For example, a machine-readable medium includes read only memory ("ROM"); random access memory ("RAM"); magnetic disk storage media; optical storage media; flash memory devices; etc.

One Embodiment of a Sensor Device

[0025] FIG. **1** is a block diagram of one embodiment of a sensor device. The sensor device may be part of a tag. Referring to FIG. **1**, sensor device **100** comprises an ambient radio-frequency (RF) energy harvester **101**, an ultra-low-power (ULP) sensor **102** (e.g., temperature, light, humidity, etc.), a micro-controller **103**, and a communication unit **104**. Although not shown, sensor device **100** includes one or more antennas. The antennas may be part of communication unit **104** or may be separate, such as in the case of an antenna used to harvest energy.

[0026] In one embodiment, RF energy harvester **101** harvests ambient RF power to run ultra-low power tags and/or sensors **102**, micro-controller **103**, and/or communication unit **104**, based on received RF input energy received by an antenna (not shown) of sensor device **100**. There are a number of sources of ambient RF power, including, but not limited to WiFi, DTV and GSM signals. Other sources of ambient RF power include, for example, toys, proprietary communication protocols, and even stray energy leakage from devices, such as microwave ovens. The antenna receiving the RF energy input may be part of communication unit **104** or a separate antenna. The antenna(s) may be designed to receive the energy in multiple frequency bands, or there may be separate antenna(s) for these different frequency bands.

[0027] In one embodiment, sensor **102** comprises an ultra-low-power (ULP) sensor and/or tag and micro-controller **103** comprises an ultra-low-power (ULP) micro-controller. Sensor **102** may comprise a temperature sensor, a light sensor, a motion sensor, air flow sensor, image sensor, accelerometer, gyroscope, gas detector, microphone, atmospheric pressure sensor, humidity sensor, mechanical pressure sensor, etc. In one embodiment, sensor **102**, as a ULP sensor, has a power requirement of 1-20 uW and a duty cycle of 1% to 10% (where the duty cycle varies in response to available energy over a period of time or the specific sensing needs, usually seconds to hours).

[0028] In one embodiment, micro-controller **103** performs control operations and/or processing for the sensor device **100**. In one embodiment, controller **103** is responsive to and receives sensor data from sensor **102** and provides it to communication unit **104** for transmission (e.g., wireless transmission) from device **100**. Controller **103** may also log sensor data for a time, and transmit the entire log to communication unit **104** for transmission later. Note that in this case the sensing rate and the communication rate can be different.

[0029] Communication unit **104** provides a communication mechanism for sensor device **100**. In one embodiment communication unit **104** is a wireless communication unit. In one embodiment, communication unit **104** has an RF transmission along with an antenna for receiving and transmitting RF signals, including RF signals transmitted with an access point or other locally positioned device.

[0030] In one embodiment, the ambient RF energy harvester is optimized for overall efficiency and a minimum of start-up power. These optimizations improve the range at which energy can be usefully harvested and improve the number of places where ambient energy is practical, particularly in view of the fact that ambient RF energy levels are small and often bursty (traffic-dependent), rectified voltages are very low (<100 mV) at typical ranges, and typical Complementary Metal Oxide Semiconductor (CMOS) loads such as MCU etc. require 800+mV to operate.

[0031] An energy harvester and method for performing energy harvesting are described. In one embodiment, the energy harvester converts incident radio frequency (RF) energy, or ambient RF energy, to direct current energy. In one embodiment, the energy harvester comprises: a first RF rectifier to output a first voltage determined by rectified RF energy in response to received RF energy; a first energy reservoir coupled to the first RF rectifier to store energy at the first voltage; a DC/DC boost converter coupled to the first energy reservoir to convert the first voltage to a second voltage; a second reservoir coupled to the DC/DC converter to store energy at the second voltage, where the second voltage is greater than the first voltage; and a third reservoir (e.g., a longer-term energy storage device such as a low-leakage capacitor or battery, etc.) coupled to the second reservoir to receive energy transferred from the second reservoir periodically.

[0032] In one embodiment, the RF rectifier comprises one selected from a group consisting of: a Schottky diode, a P-N junction diode, a diode-connected field effect transistor, and a tunnel diode.

[0033] In one embodiment, the first reservoir comprises a capacitor with a capacitance value determined at least in part by the envelope of the received RF energy. In one embodiment, the first reservoir comprises a capacitor having a value based on stored energy above a threshold voltage given ambient RF input power and a duty cycle of the input power. In another embodiment, the first reservoir comprises a first capacitor and the second reservoir comprises a second capacitor, wherein capacitance of the second capacitor is approximately equal to a product of the first capacitor capacitance times a square of a ratio of an expected value of the second voltage divided by an expected value of the first voltage.

[0034] In one embodiment, the second reservoir comprises an inductor used to boost the voltage, wherein energy stored in the inductor is approximately equal to energy stored in the first reservoir.

[0035] In one embodiment, the DC/DC boost converter comprises a self-excited oscillator. In one embodiment, the self-excited oscillator comprises a transistor coupled to a transformer. In one embodiment, the frequency of the self-excited oscillator is controlled at least in part by an envelope of the received RF energy. In one embodiment, the DC/DC converter is a switch mode converter with switching intervals controlled at least in part by an envelope of the received RF energy.

[0036] In one embodiment, the third reservoir is coupled to the second reservoir via a switch, which is closed periodically to transfer energy from the second reservoir to the third reservoir. In one embodiment, the switch is controlled at least in part by the envelope of the received RF energy. In one embodiment, the third reservoir is coupled to a load, and the first voltage is insufficient to operate the load directly, and the third voltage is sufficient to operate the load. In one embodiment, the third reservoir has an energy storage capacity that is greater than an energy storage capacity of the second reservoir.

[0037] FIG. **2** is a block diagram of one embodiment of an RF energy harvester. Referring to FIG. **2**, RF energy harvester **200** comprises RF rectifier **201**, a first direct current (DC) reservoir (storage) **202**, a boost converter and second reservoir **203**, a third reservoir **204**, and control logic **205**.

[0038] RF rectifier **201** receives ambient RF energy input received from an antenna and rectifies the RF energy to produce a DC voltage.

[0039] First DC reservoir **202** stores the voltage generated from the rectified RF signals received by device **100**. In one embodiment, reservoir **202** comprises a capacitor. In one embodiment, the size (value) of the capacitor that is selected for use is based on the stored energy above a voltage threshold for the ambient RF input power.

[0040] Second DC reservoir **203** receives the voltage and increases the voltage. To increase the voltage, second DC reservoir **203** includes a DC/DC converter. In one embodiment, the DC/DC converter comprises a boost converter which includes a self-excited oscillator for operation. The self-excited oscillator includes a junction field effect transistor (JFET) coupled with a transformer. In one embodiment, the amount of the boost conversion is a function of the input energy, and the DC/DC converter is designed to maximize the output voltage as a function of input voltage in this low-energy environment. FIG. **7** illustrates one embodiment of a self-excited oscillator. FIG. **8** illustrates one embodiment of a charger schematic that receives the output of the boost converter, such as, for example, the one shown in FIG. **7**.

[0041] The upconverted voltage from the DC/DC converter is stored in a storage device of second reservoir **203**. In one embodiment, second reservoir **203** uses a capacitor to store the upconverted voltage. In another embodiment, second reservoir **203** uses an inductor to store the upconverted voltage, but this is a much shorter-term storage option.

[0042] When the energy stored in second reservoir **203** reaches a certain level, the energy is transferred to a third reservoir (not shown). Thus, the transfer occurs periodically at a rate determined by the amount of input energy. In one embodiment, the third reservoir comprises a battery, a capacitor, a supercap, etc. The third reservoir provides DC energy to a load.

[0043] In one embodiment, the load comprises a sensor, processor or microcontroller, and/or a communication unit. In one embodiment, the DC voltage from the third reservoir is able to run the load, while the voltage produced by rectifier **201** would not be able to do so.

[0044] Control logic **205** controls the energy harvesting process. In one embodiment, control logic **205** comprises a separate unit that generates control signals to control each of the reservoirs **202-3203**. In another embodiment, the control is distributed through various discrete gating components such that a separate control unit is not necessary but the function is still performed.

[0045] FIG. **3** is another more detailed block diagram of one embodiment of an RF energy harvester. Referring to FIG. **3**, RF energy harvester **300** comprises RF rectifier **301**, a first direct current (DC) reservoir (storage) **302**, second reservoir **303**, and a third reservoir **304**. In one embodiment, the input to RF rectifier **301** is an RF input from an antenna on the sensor device. RF rectifier **301** converts the RF input signals to a voltage. In one embodiment, the voltage may range between 10 mV and 500 mV. The voltage is stored in reservoir **302**. In one embodiment, reservoir **302** comprises a ceramic capacitor 1 uF to 100 uF or more.

[0046] In one embodiment, the stored energy from reservoir **302** is transferred to second reservoir **303** via a transistor **311**, self-gated as the voltage rises in reservoir **302**. In one embodiment, second reservoir **303** comprises a boost converter **303**A. The boost converter **303**A operates to upconvert the voltage stored in reservoir **302** and store that upconverted voltage into reservoir **303**B.

[0047] The energy stored in second reservoir **303** is transferred to third reservoir **304**. In one embodiment, third reservoir **304** comprises a tantalum capacitor, supercap 100 uF to 1 F or a battery. In one embodiment, transistor **312** (e.g., a FET) couples second reservoir **303** to third reservoir **304**, which turns on when second reservoir **303** reaches an optimal voltage. In one embodiment, transistor **312** is controlled at least in part by the envelope of the received RF energy such that when the voltage stored in reservoir **303**B reaches a certain watermark level, transistor **312** closes/turns on and the energy is transferred. In one embodiment, through the selection of high gate-threshold transistors, the voltage can build up fairly high in reservoir **303** (as much as 1-2V) before the transistor **312** closes/turns on. Transistor **312** closes/turns on automatically when the gate threshold of the transistor design is reached in reservoir **303**. As soon as transistor **312** closes/turns on, the energy is transferred from reservoir **303** into reservoir **304**, thus depleting the energy in reservoir **303**, and the gate threshold falls below the watermark level and the transistor **312** closes/opens again. The process then repeats when the voltage in reservoir **303** becomes sufficiently high.

[0048] Note that transistor **311** and **312** may be replaced with other types of switches.

Waveform Aware Harvesting

[0049] In one embodiment, the RF waveform harvester comprises a RF to DC converter that is optimized for use with non-continuous wave (CW) signals. In another embodiment, the RF waveform harvesters are waveform aware and are able to perform ambient energy harvesting based on a waveform model, where the available RF energy is in the form of communication waveforms of a variety of types. Examples of commonly-harvested ambient RF energy sources with non-continuous wave signals include, but are not limited to, digital television (DTV) broadcasts, cellular base station transmissions (e.g., GSM, Code Division Multiple Access (CDMA)), Wi-Fi transmissions, etc.

[0050] For example, in one embodiment, WiFi is the communications waveform that is the ambient form of energy to be harvested. WiFi is bursty and has low amplitude compared to other sources of energy, where a bursty signal has a high peak to average ratio over ms to s time scale. For example, some WiFi signals have WiFi transmission burst times on the order of 1 ms. For a bursty signal, the harvester can only contribute energy to the reservoir capacitor (C_X) when the ambient source is transmitting.

[0051] FIG. **4** illustrates a diode-based harvester schematic. Referring to FIG. **4**, in one embodiment, the harvester is designed to be well matched at input power levels below −20 dBm where the majority of ambient Wi-Fi signals are expected to fall. Thus, harvester is characterized both in terms of its input match from 2.4 GHz to 2.5 GHz, as well as for harvesting efficiency at its maximum power point (MPP). Harvesting efficiency is defined as the ratio of input RF power at the harvester to harvested DC power at the load (η=PDC/PRF).

[0052] The purpose of capacitor C_X in FIG. **4** is to store charge for any subsequent active electronic circuitry. In one embodiment, typical circuit power-up threshold voltages V_{TH} equals 0.8 V, as is typical for CMOS logic in commodity processes. In another embodiment, the power-up threshold voltages V_{TH} equals 50 mV, as is typical for ultra-low startup voltage boost converters using JFETs. Alternatively, specially doped CMOS transistors, floating gate devices, or Silicon on Insulator (SOI) transistors may be capable of operation down to voltages approaching V_{TH}=50-100 mV as well.

[0053] If the usable energy is defined as the portion of the stored energy above some threshold voltage V_{TH}, the following describes how to find a value of C_X given the ambient RF input power and the signal's duty cycle. This is based on the maximum power point curve for the harvester, the typical burst timings for the ambient signal of interest (e.g., WiFi with some traffic model), and a time domain response for the harvester as a function of C_X. Thus, in one embodiment, the storage capacitor selection C_X is optimized on the time scale of network traffic for the signal being harvested.

[0054] FIG. **5** illustrates a diode output circuit model. Because the diode is a non-linear device, the power delivered to the load varies dramatically with load impedance. The Maximum Power Point Tracking (MPPT) circuit functions as a load impedance converter to maximize the power delivered to the load, given a particular nonlinear operating point.

[0055] Referring to FIG. **5**, the diode output model consists of an open-circuit voltage V_{source} along with a nonlinear source resistance R_{source}. The pair, V_{source}, R_{source}, represents a fixed operating point at maximum power-point (MPP). The load resistance R_{load} includes any leakage currents in C_X as well as the quiescent current of the active circuitry attached to the harvester. In other words, the load impedance R_{load} is chosen a priori based on the MPP of the harvester at a given ambient signal level (the maximum power point of the harvester given the input power). Using this model, only the effect of varying C_X (not other system conditions) is considered.

[0056] FIG. **6**A illustrates the usable energy stored in capacitor C_X during one transmission burse of duration T_p. Referring to FIG. **6**A, the usable energy in C_X is represented as the shaded portion of the curve above the voltage threshold and below the voltage across the capacitor.

[0057] FIG. **6**B illustrates examples of good and bad choices of C_X. If C_X is too large, the active circuitry will never be powered because the input energy is insufficient to generate voltage above the threshold. On the other hand, if C_X is minimized, little energy will be stored in the reservoir C_X and the runtime of the active circuitry will not extend beyond the transmission intervals of the RF source. Referring to FIG. **6**, harvesters 'A' and 'B' represent different choices for C_X with the same conditions otherwise. In harvester A, C_X looks appropriate as the output voltage exceeds V_{TH} during each burst, while in harvester B, C_X is too big and the output voltage never exceeds V_{TH} so there is no usable energy.

[0058] An expression is derived for the useful-energy-maximizing reservoir capacitance C_X as a function of ambient RF signal duty cycle and the load impedance RL at a diode harvester's maximum power point. The expression may be used to calculate the usable energy as a function of the known parameters and the unknown capacitance C_X.

[0059] The total energy in C_X may be expressed as follows:

$$E = \frac{1}{2}CV^2$$

where C is the capacitance and V is the terminal voltage of C_X. It is assumed that the energy stored on the capacitor is only usable when the capacitor voltage is above the desired threshold V_{TH}. The usable energy is thus the difference between the stored energy at the end of an RF transmission (at time t=T_p) and the stored energy when C_X is charged only to V_{TH} and is expressed as follows:

$$E_{usable} = \frac{1}{2}C\left[V_{T_p}^2 - V_{th}^2\right]$$

[0060] where V_{Tp} is the terminal voltage on C_X at the end of an RF transmission (e.g., at the end of each burst) of duration T_p and is expressed as:

$$V_{T_p} = V_{src}(1 - e^{-T_p/R_LC})$$

[0061] By substitution, the equation for the usable energy may be re-written in terms of C and the known values of R_L, V_{Th} and T_p as follows:

$$E_{usable} = \frac{1}{2}CV_{T_p}^2\left[e^{-\frac{2T_p}{R_LC}} - 2e^{-\frac{T_p}{R_LC}} + \left(1 - \left(\frac{V_{th}}{V_{T_p}}\right)^2\right)\right]$$

The equation may be solved for E_{usable} as a function of C_X.

[0062] Thus, a new class of RF energy harvesters, referred to herein as waveform aware harvesters, have been described.

These RF energy harvesters are RF to DC converters that are optimized for their performance with non-CW signals.

[0063] Whereas many alterations and modifications of the present invention will no doubt become apparent to a person of ordinary skill in the art after having read the foregoing description, it is to be understood that any particular embodiment shown and described by way of illustration is in no way intended to be considered limiting. Therefore, references to details of various embodiments are not intended to limit the scope of the claims which in themselves recite only those features regarded as essential to the invention.

We claim:

1. An energy harvester to convert incident radio frequency (RF) energy to direct current energy, the energy harvester comprising:

a first RF rectifier to output a first voltage determined by rectified RF energy in response to received RF energy;

a first energy reservoir coupled to the first RF rectifier to store energy at the first voltage;

a DC/DC converter coupled to the first energy reservoir to convert the first voltage to a second voltage;

a second reservoir coupled to the DC/DC converter to store energy at the second voltage, the second voltage being greater than the first voltage; and

a third reservoir coupled to the second reservoir to receive energy transferred from the second reservoir periodically.

2. The energy harvester defined in claim **1** wherein the third reservoir is coupled to the second reservoir via a first switch, the first switch being closed periodically to transfer energy from the second reservoir to the third reservoir.

3. The energy harvester defined in claim **2** wherein the first switch is controlled at least in part by the envelope of the received RF energy.

4. The energy harvester defined in claim **1** wherein the third reservoir is coupled to a load.

5. The energy harvester defined in claim **4** wherein the first voltage is insufficient to operate the load directly, and the third voltage is sufficient to operate the load.

6. The energy harvester defined in claim **1** wherein the DC/DC converter comprises a self-excited oscillator.

7. The energy harvester defined in claim **6** wherein frequency of the self-excited oscillator is controlled at least in part by an envelope of the received RF energy.

8. The energy harvester defined in claim **1** wherein the DC/DC converter comprises a boost converter.

9. The energy harvester defined in claim **1** wherein the first reservoir comprises a capacitor with a capacitance determined at least in part by the envelope of the received RF energy.

10. The energy harvester defined in claim **1** wherein the first reservoir comprises a first capacitor and the second reservoir comprises a second capacitor, wherein capacitance of the second capacitor is approximately equal to a product of the first capacitor capacitance times a square of a ratio of an expected value of the second voltage divided by an expected value of the first voltage.

11. The energy harvester defined in claim **1** wherein the DC/DC converter is a switch mode converter with switching intervals controlled at least in part by an envelope of the received RF energy.

12. The energy harvester defined in claim **1** wherein the RF rectifier comprises one or more diodes selected from a group consisting of: a Schottky diode, a P-N junction diode, a diode-connected field effect transistor, and a tunnel diode.

13. The energy harvester defined in claim **1** wherein the third reservoir has an energy storage capacity that is greater than an energy storage capacity of the second reservoir.

14. The energy harvester defined in claim **1** wherein the second reservoir comprises an inductor, wherein energy stored in the inductor is approximately equal to energy stored in the first reservoir.

15. The energy harvester defined in claim **1** wherein the first reservoir comprises a capacitor having a value based on stored energy above a threshold voltage given ambient RF input power and a duty cycle of the input power.

16. A device comprising:

an antenna;

a load; and

an energy harvester coupled to the antenna and the load, wherein the energy harvester comprises

a first RF rectifier to output a first voltage determined by rectified RF energy in response to received RF energy;

a first energy reservoir coupled to the first RF rectifier to store energy at the first voltage;

a DC/DC converter coupled to the first energy reservoir to convert the first voltage to a second voltage;

a second reservoir coupled to the DC/DC converter to store energy at the second voltage, the second voltage being greater than the first voltage; and

a third reservoir coupled to the second reservoir to receive energy transferred from the second reservoir periodically.

17. The device defined in claim **16** wherein the third reservoir is coupled to the second reservoir via a switch, the switch being closed periodically to transfer energy from the second reservoir to the third reservoir.

18. The device defined in claim **16** wherein the third reservoir is coupled to a load, and wherein the first voltage is insufficient to operate the load directly, and the third voltage is sufficient to operate the load.

19. The device defined in claim **16** wherein the DC/DC converter comprises a boost converter.

(57) **ABSTRACT**

A rectenna includes (a) a multi-band multi-channel (MBMC) matching network, and/or (b) an adaptively reconfigurable rectifier or a breakdown-protected rectifier. An MBMC matching network includes a plurality of T-shaped transmission line matching structures coupled in series. An adaptively reconfigurable rectifier circuit includes a low input power rectifying portion, a high high input power rectifying portion, and a set of transistors configured for selectively and automatically transitioning the adaptively reconfigurable rectifier between a low input power operating configuration and a high input RF power operating configuration, in a manner correlated with input RF power level. A breakdown-protected rectifier includes a transistor-protected diode structure having a diode coupled to a transistor in a manner that protects the diode from direct exposure to negative voltages that would ordinarily cause the diode to break down in the absence of the transistor.

RECTENNA CIRCUIT ELEMENTS, CIRCUITS, AND TECHNIQUES FOR ENHANCED EFFICIENCY WIRELESS POWER TRANSMISSION OR AMBIENT RF ENERGY HARVESTING

TECHNICAL FIELD

[0001] Aspects of the present disclosure are directed to rectenna circuit elements, circuits, and techniques for enhancing power conversion efficiency (PCE) in wireless power transmission (WPT) or ambient RF energy harvesting circuits by way of (a) a multi-band multi-channel (MBMC) RF matching network, and/or (b) an extended input power range rectifier, which can include an adaptively reconfigurable rectifier or a breakdown-protected rectifier.

BACKGROUND

[0002] Wireless Power Transfer (WPT) involves the transfer of RF electrical energy from a predetermined source, or particular types or sources, to a receiving antenna that is coupled to a rectifier. The combination of the receiving antenna and the rectifier is known as a rectenna. The rectenna converts received RF energy into DC power, which can be used to power a system or device, such as a sensor or a medical device. Ambient RF energy harvesting involves the collection of RF energy that is inherently present in modern environments as a result of wireless communication between one or more types of wireless systems and devices (e.g., public wireless telecommunication base stations and mobile telephones/smartphones), such that RF energy which would otherwise be wasted can be put to use, such as for battery recharging. As with WPT, ambient RF energy harvesting relies upon a rectenna, which converts harvested RF energy into DC power.

[0003] FIG. **1** is a schematic illustration of a conventional rectenna that is configured for receiving RF energy within a single RF frequency band, and converting RF energy within this single frequency band to DC power. Because this rectenna is limited to a single RF frequency band, RF energies outside of the single frequency band for which the rectenna is designed cannot be converted into DC power, thereby limiting the utility of this conventional rectenna in WPT and/or RF energy harvesting applications. For instance, various types of implantable medical devices, such as implantable pulse generators, have a power source such as a battery that needs to be recharged. For implanted medical devices, instantaneous RF power applied to the human body must be maintained below a predetermined level for safety purposes. Hence, it is desirable to utilize multiple RF frequency bands to apply pulsed RF power in a simultaneous manner for recharging implanted power sources. Additionally, for RF energy harvesting applications, it is desirable to simultaneously harvest RF energy within multiple frequency bands in a simultaneous manner, in order to enhance or maximize the conversion of available ambient RF energy into DC power.

[0004] Multi-frequency rectennas have been developed; however, such rectennas typically utilize multiple antennas and multiple rectifiers, with each antenna and its associated rectifier corresponding to a particular RF frequency band. Consequently, such conventional multi-frequency rectenna designs result in less efficient RF energy conversion, and increased space and cost.

[0005] The RF-to-DC power conversion efficiency of a rectenna critically depends on the nature of the rectifier therein. FIG. **2**A is a schematic illustration of a conventional rectenna based upon a conventional rectifier, which is suitable for low. RF input power conditions. More particularly, for this rectenna, RF-to-DC power conversion efficiency (PCE) increases linearly with input RF power until input RF power exceeds the breakdown voltage of diode D**1**, after which RF-to-DC PCE degrades rapidly.

[0006] FIG. **2**B is a schematic illustration of a conventional rectenna that utilizes a conventional high RF input power rectifier. For the rectenna of FIG. **2**B, a set of diodes D**2** (e.g., a total of four diodes, arranged pairwise in parallel) is coupled in series with diode D**1**, thereby extending the overall breakdown voltage of the combination of diode D**1** and the set of diodes D**2**. Unfortunately, this rectenna exhibits undesirably low RF-to-DC PCE at low input RF power levels.

[0007] FIG. **2**C is a schematic illustration of conventional rectenna that utilizes another type of conventional low RF input power rectifier. Here again, once the input RF power exceeds the breakdown voltage of diode D**1**, the RF-to-DC PCE of this rectenna degrades rapidly.

[0008] A need exists for a rectenna that utilizes a single antenna and a single rectifier, and which exhibits enhanced RF-to-DC PCE across a significantly wider range of input RF operating power conditions compared to prior rectennas.

BRIEF DESCRIPTION OF THE DRAWINGS

[0009] FIG. **1** is a schematic illustration of a conventional rectenna

[0010] FIG. **2**A is a schematic illustration of a conventional rectenna that utilizes a conventional low RF input power rectifier.

[0011] FIG. **2**B is a schematic illustration of a conventional rectenna that utilizes a conventional high RF input power rectifier.

[0012] FIG. **2**C is a schematic illustration of a conventional rectenna that utilizes another conventional low RF input power rectifier.

[0013] FIG. **3** is a schematic illustration of a representative multi-band multi-channel (MBMC) rectenna, which includes an MBMC matching network in accordance with an embodiment of the present disclosure.

[0014] FIG. **4**A is a top schematic illustration of a quasi-Yagi antenna 1×2 subarray in accordance with an embodiment of the present disclosure.

[0015] FIG. **4**B is a front or top side image of a 1×4 quasi-Yagi antenna array having a bandwidth that covers each of the GSM-1800 and UTMS-2100 frequency bands, which is formed by connecting two quasi-Yagi 1×2 antenna subarrays of FIG. **4**A together with a T-junction power divider in accordance with an embodiment of the present disclosure.

[0016] FIG. **4**C is a back or bottom side image of the 1×4 quasi-Yagi antenna array of FIG. **4**B.

[0017] FIG. **5**A is a schematic illustration of a representative embodiment of an MBMC matching network within an MBMC rectenna in accordance with an embodiment of the present disclosure.

[0018] FIG. **5**B is an image of an as-fabricated representative implementation of this MBMC matching network in accordance with an embodiment of the present disclosure.

[0019] FIG. **6** plots measured RF-to-DC PCE against frequency at different power levels (−30 dBm to −18 dBM) for a representative implementation of the MBMC rectenna of FIG. **3**.

[0020] FIG. **7** plots measured PCE against single and dual-tone input power for input signal frequencies of 1.83 GHz and 2.14 GHz, which are the approximate center frequencies of the 1.80-1.88 GHz and 2.11-2.17 GHz frequency bands, for the representative implementation of the MBMC rectenna of FIG. **3**.

[0021] FIG. **8**A is a schematic illustration of an adaptively reconfigurable rectenna or adaptive rectenna based upon a first adaptively reconfigurable rectifier or first adaptive rectifier in accordance with an embodiment of the present disclosure.

[0022] FIG. **8**B is a schematic illustration of an adaptively reconfigurable rectenna or adaptive rectenna based upon a second adaptively reconfigurable rectifier or second adaptive rectifier in accordance with an embodiment of the present disclosure.

[0023] FIG. **8**C illustrates a circuit configuration of a representative implementation of an adaptively reconfigurable rectifier shown FIG. **8**B.

[0036] FIG. **16** is a graph illustrating simulated RF-to-DC PCE versus input RF power for representative implementations of each of (a) the conventional low input RF power rectifier of FIG. **2**A; (b) the MBMC rectifier of FIG. **3**; (c) the second adaptively reconfigurable rectifier shown in FIG. **8**B; (d) the MBMC matching network coupled to the second adaptively reconfigurable rectifier **352**, in a manner shown in FIG. **15**A; (e) the breakdown-protected rectifier of FIG. **10**A; and (f) the MBMC matching network coupled to the breakdown-protected rectifier **402**, in a manner shown in FIG. **15**B.

[0037] FIGS. **17**A-**17**H are block diagrams illustrating representative types of wireless networks in which a set of rectennas, including one or more MBMC rectennas, adaptively reconfigurable rectennas, and/or breakdown-protected rectennas, in accordance with an embodiment of the present disclosure can be deployed.

SUMMARY

[0038] In accordance with an aspect of the present disclosure, a circuit configured for receiving RF energy distributed in multiple RF frequency bands includes a multi-band multichannel (MBMC) matching network. The MBMC matching network includes: a plurality of T-shaped transmission line matching structures, each T-shaped transmission line matching structure coupled in series to another T-shaped transmission line matching structure, wherein each T-shaped transmission line matching structure includes a first portion, a second portion, and a third portion coupled between the first portion and the second portion, and wherein the first portion of a first T-shaped transmission line matching structure within the plurality of T-shaped transmission line structures forms an input of the MBMC matching network, the second portion of a second T-shaped transmission line matching structure within the plurality of T-shaped transmission line matching structures forms an output of the MBMC matching network, and the third portion of at least one T-shaped transmission line matching structure within the plurality of T-shaped transmission line matching structures is couplable to electrical ground.

[0039] Each individual T-shaped transmission line matching structure within the MBMC matching network is configured for providing an impedance match corresponding to RF frequencies within a particular RF frequency band. The circuit can form a portion of a wireless power transmission (WPT) system or a portion of an ambient RF energy harvesting system.

[0040] The circuit can include or be a rectenna, which includes: an antenna coupled, to the input of the MBMC matching network; and a rectifier coupled to the output of the MBMC matching network. The rectifier includes one of: (a) an adaptively reconfigurable rectifier having a low input RF power rectifying portion, a high input RF power rectifying portion, and a set of transistors coupled to one of the high input RF power rectifying portion the low input RF power rectifying portion, the set of transistors configured for automatically transitioning the adaptively reconfigurable rectifier between a low input RF input power operating configuration and a high input RF power operating configuration based upon input RF power level; and (b) a breakdown-protected rectifier having at least transistor-protected diode structure, the transistor-protected diode structure comprising at least one diode coupled to a transistor in a manner that protects the diode from direct exposure to negative voltages that would ordinarily cause the diode to break down in the absence of the transistor.

[0041] In accordance with another aspect of the present disclosure, a circuit configured for rectifying signals (e.g., wirelessly received RF signals) includes one of: (a) an adaptively reconfigurable rectifier having a low input power rectifying portion, a high input power rectifying portion, and a set of transistors coupled to one of the high input power rectifying portion the low input power rectifying portion, the set of transistors configured for selectively and automatically transitioning the adaptively reconfigurable rectifier between a low input power operating configuration and a high input RF power operating configuration in a manner correlated with a power level of a signal input to the circuit; and (b) a breakdown-protected rectifier having at least one transistor-protected diode structure, the at least one transistor-protected diode structure comprising a first diode coupled to a transistor in a manner that protects the first diode from direct exposure to negative voltages that would ordinarily cause the diode to break down in the absence of the transistor.

[0042] In various embodiments, the low input power portion and the high input power portion of the adaptively reconfigurable rectifier are coupled in series, and the set of transistors of the adaptively reconfigurable is be coupled in parallel with the high input power portion. A control terminal of each transistor within the set of transistors is coupled to electrical ground. The set of transistors of the adaptively reconfigurable rectifier can include a plurality of transistors coupled to each other in series. Each transistor within the set of transistors can be a Field Effect Transistor (FET) (e.g., a MOSFET, a MESFET, or another type of FET).

[0043] In various embodiments, the low input power rectifying portion of the adaptively reconfigurable rectifier includes a first set of diodes, and the high input power rectifying portion includes a second set of diodes. At least one of the first set of diodes and the second set of diodes can include a plurality of diodes.

[0044] The breakdown-protected rectifier includes a first transistor-protected diode structure including a first diode and a transistor, wherein the transistor includes a control terminal coupled to the anode of the first diode, a first terminal coupled to the cathode of the first diode, and a second terminal couplable to circuitry external to the transistor-protected diode structure. The anode of the first diode is coupled to an input of the breakdown-protected rectifier and is configured to receive an alternating current (AC) signal, and wherein the second terminal of the transistor is coupled to an output of the breakdown-protected rectifier.

[0045] The transistor-protected diode structure can further include a second diode coupled in parallel with the second terminal and the third terminal of the transistor, such that the anode of the second diode is coupled to the cathode of the first diode. The transistor-protected diode structure can additionally or alternatively includes another diode having its anode coupled to the anode of the first diode, and its cathode coupled to the control terminal of the transistor.

[0046] In some embodiments, the breakdown-protected rectifier includes the first transistor-protected diode structure combined with a second transistor-protected diode structure coupled in a cascaded manner to the first transistor-protected diode structure, such that a negative voltage across the combination of the first and second transistor-protected diode structures is distributed across the transistor of the first transistor-protected diode structure and a transistor of the second transistor-protected diode structure. The second transistor-protected diode structure includes a first diode and a transistor having a control input, a first terminal, and a second terminal, wherein the anode of the first diode of the second transistor-protected diode structure is coupled to the anode of the first diode of the first transistor-protected diode structure, the cathode of the first diode of the second transistor-protected diode structure is coupled to the second terminal of the transistor of the second diode-protected transistor structure, and the third terminal of the transistor of the second diode-protected transistor structure is coupled to the control input of the transistor of the first diode-protected transistor structure.

[0047] In accordance with another aspect of the present disclosure, a wireless network includes: a transmission (TX) stage configured for wirelessly transmitting electromagnetic signals; and a reception (RX) stage configured for receiving electromagnetic signals transmitted by the TX stage. The RX stage includes one of: (a) a multi-band multi-channel (MBMC) matching network having: a plurality of T-shaped transmission line matching structures, each T-shaped transmission line matching structure coupled in series to another T-shaped transmission line matching structure, wherein each T-shaped transmission line matching structure includes a first portion, a second portion, and a third portion coupled between the first portion and the second portion, and wherein the first portion of a first T-shaped transmission line matching structure within the plurality of T-shaped transmission line structures forms an input of the MBMC matching network, the second portion of a second T-shaped transmission line matching structure within the plurality of T-shaped transmission line matching structures forms an output of the MBMC matching network, and the third portion of at least one T-shaped transmission line matching structure within the plurality of T-shaped transmission line matching structures is couplable to electrical ground; (b) an adaptively reconfigurable rectifier having a low input power rectifying portion, a high input power rectifying portion, and a set of transistors coupled to one of the high input power rectifying portion the low input power rectifying portion, the set of transistors configured for selectively and automatically transitioning the adaptively reconfigurable rectifier between a low input power operating configuration and a high input RF power operating configuration in a manner correlated with a power level of a signal input to the RX stage; and (c) a breakdown-protected rectifier having at least one transistor-protected diode structure, the at least one transistor-protected diode structure comprising a first diode coupled to a transistor in a manner that protects the first diode from direct exposure to negative voltages that would, ordinarily cause the diode to break down in the absence of the transistor. In some embodiments, the RX stage includes the MBMC matching network and one of the adaptively reconfigurable rectifier and the breakdown-protected rectifier.

[0048] The wireless network can further include one or more repeater/amplification stages configured to receive electromagnetic signals from the TX stage and transmit electromagnetic signals to the RX stage. One or more of the repeater/amplification: stages include one of: (a) a multi-band multi-channel (MBMC) matching network having: a plurality of T-shaped transmission line matching structures, each T-shaped transmission line matching structure coupled in series to another T-shaped transmission line matching structure, wherein each T-shaped transmission line matching structure includes a first portion, a second portion, and a third portion coupled between the first portion and the second portion, and wherein the first portion of a first T-shaped transmission line matching structure within the plurality of T-shaped transmission line structures forms an input of the MBMC matching network, the second portion of a second T-shaped transmission line matching structure within the plurality of T-shaped transmission line matching structures forms an output of the MBMC matching network, and the third portion of at least one T-shaped transmission line matching structure within the plurality of T-shaped transmission line matching structures is couplable to electrical ground; (b) an adaptively reconfigurable rectifier having a low input power rectifying portion, a high input power rectifying portion, and a set of transistors coupled to one of the high input power rectifying portion the low input power rectifying portion, the set of transistors configured for selectively and automatically transitioning the adaptively reconfigurable rectifier between a low input power operating configuration and a high input RF power operating configuration in a manner correlated with a power level of a signal input to the RX stage; and (c) a breakdown-protected rectifier having at least one transistor-protected diode structure, the at least one transistor-protected diode structure comprising a first diode coupled to a transistor in a manner that protects the first diode from direct exposure to negative voltages that would ordinarily cause the diode to break down in the absence of the transistor. In some embodiments, at least one repeater/amplification stage includes an MBMC matching network and one of an adaptively reconfigurable rectifier and a breakdown-protected rectifier.

DETAILED DESCRIPTION

[0049] In the present disclosure, depiction of a given element or consideration or use of a particular element number in a particular FIG. or a reference thereto in corresponding descriptive material can encompass the same, an equivalent, or an analogous element or element number identified in another FIG. or descriptive material associated therewith. The use of "/" in a FIG. or associated text is understood to mean "and/or" unless otherwise indicated. The recitation of a particular numerical value or value range herein is understood to include or be a recitation of an approximate numerical value or value range, for instance, to within +/−20%, +/−15%, +/−10%, or +/−5%.

[0050] As used herein, the term "set" corresponds to or is defined as a non-empty finite organization of elements that mathematically exhibits a cardinality of at least 1 (i.e., a set as defined herein can correspond to a unit, singlet, or single element set, or a multiple element set), in accordance with known mathematical definitions (for instance, in a manner corresponding to that described in *An Introduction to Mathematical Reasoning: Numbers, Sets, and Functions*, "Chapter 11: Properties of Finite Sets" (e.g., as indicated on p. 140), by Peter J. Eccles, Cambridge University Press (1998)). In general, an element of a set can include or be a system, an apparatus, a device, a structure, an object, a circuit, a circuit element, a process, a physical parameter, or a value depending upon the type of set under consideration.

[0051] Embodiments in accordance with the present disclosure are directed to rectenna circuit elements, circuits, and techniques that facilitate or enable enhanced power conversion efficiency (PCE) in wireless power transmission (WPT) or ambient RF energy harvesting systems, devices, or circuits. More particularly, systems, devices, or circuits in accordance with various embodiments of the present disclosure include rectennas having (a) a multi-band multi-channel (MBMC) RF matching network, and/or (b) an extended input power range rectifier, which can include an adaptively reconfigurable rectifier circuit, or a breakdown-protected rectifier circuit, as further detailed below.

[0052] Representative Rectenna with MBMC Matching Network

[0053] FIG. **3** is a schematic illustration of a representative multi-band multi-channel (MBMC) rectenna **100** in accordance with an embodiment of the present disclosure. The MBMC rectenna **100** includes an antenna or antenna structure **110** configured for receiving RF energy corresponding to or spanning multiple RF frequency bands. The antenna **100** includes an output coupled to an input of an MBMC matching network **200**, such that RF energy received by the antenna **110** is delivered to the MBMC matching network **200**. The MBMC matching network **200** includes an output coupled to an input of a rectifier **120**, which has an output coupled to an input of a DC pass filter or RF choke **130**, and which further has an output coupled to a load resistance **140**. Taken together, the MBMC matching network **200** and the rectifier **120**, possibly in combination with the DC pass filter **130** and the load resistance **140**, can be considered as or defined to be an MBMC rectifier **102**.

[0054] The antenna **110** has a bandwidth spanning multiple RF frequency bands, for instance, multiple predetermined frequency bands suitable for a particular WPT application or an intended or expected RF energy harvesting environment under consideration. For instance, depending upon embodiment details, the antenna **110** can have a bandwidth suitable for receiving RF energy spanning multiple center frequencies across multiple frequency bands that are suitable or allocated for (a) recharging one or more types of implantable/implanted medical devices, such that the MBMC rectenna **100** can form a portion of a system, device, or circuit for WPT based medical device recharging; and/or (b) public/mobile telephony or wireless network communications, such that the MBMC rectenna **100** can form a portion of a system, device, or circuit for harvesting ambient RF energy corresponding to mobile telephony or other types of wireless communication signals that are known or expected to exist in a given modern urban environment.

[0055] To aid understanding, in a representative modern urban environment at the National University of Singapore campus, ambient power density was measured by way of a conventional wideband horn antenna (0.8-18 GHz) and a conventional spectrum analyzer. It was found that the ambient power density was dominated by downlink channel power in three public communication bands, namely, GSM-900, GSM-1800, and UTMS-2100, with corresponding measured values given in Table 1

TABLE 1

Measured Ambient Power Density across Each Channel of Different Public Telecommunication Bands

Band	Downlink Frequency (MHz)	Received Power (dBm)	Antenna Gain (dBi)	Power Density ($\mu W/m^2$)
GSM-900	925-960	−40~−30	2	7.1~71.4
GSM-1800	1805-1880	−30~−20	10	45.2~452.3
UTMS-2100	2110-2170	−30~−20	10	61.6~615.8

[0056] Furthermore, Table 1 indicates that the power densities in the GSM-1800 and UTMS-2100 bands were significantly larger than the power density in the GSM-900 band. Additionally, the total RF power of all ambient communication bands that the horn antenna received was measured by a power meter, which indicated a total ambient RF power of approximately −20 to −17 dBm (or approximately 10-20 μW).

[0057] To further aid understanding, in a representative implementation directed to capturing RF power in the GSM-1800 and UTMS-2100 bands, the antenna **110** has a bandwidth that covers the Global System for Mobile (GSM) 1800 MHz frequency band, as well as the Universal Mobile Telecommunication System (UMTS) 2100 MHz frequency band. FIG. **4**A is a top schematic illustration of a quasi-Yagi antenna 1×2 subarray, which indicates corresponding quasi-Yagi 1×2 antenna subarray design parameters. Two quasi-Yagi 1×2 antenna subarrays can be connected together with a T-junction power divider to form a 1×4 quasi-Yagi antenna array.

[0058] FIG. **4**B is a front or top side image of a 1×4 quasi-Yagi antenna array, and FIG. **4**C is a back or bottom side image of the 1×4 quasi-Yagi antenna array in accordance with an embodiment of the present disclosure, which forms an antenna **110** having a bandwidth that covers each of the GSM-1800 and UMTS-2100 bands. More particularly, using values for the 1×2 quasi-Yagi antenna sub-array parameters indicated in FIG. **4**A, in millimeters, of a=190, b=100, W_1=1.2, W_2=4.4, W_{gnd}=20, L_{dri}=37, W_{dri}=8, L_{dir}=50, W_{dri}=0.5, S_{dir}=26, S_{dri}=24, and d=100, the 1×4 quasi-Yagi antenna array exhibits a −10 dB bandwidth from approximately 1.8 GHz to 2.2 GHz as indicated in FIG. **4**D, which illustrates simulated and measured $|S_{11}|$ and gain of this representative implementation of the antenna **110**. An individual having ordinary skill in the relevant art will readily recognize that the antenna **110** can exhibit other parameter values or other types of designs, based upon an intended rectenna application or environment under consideration, and a plurality of RF frequency bands associated therewith. For instance, in an RF energy harvesting application, the antenna **110** can be a conventional broadband or wideband antenna, such as a wideband horn antenna.

[0059] The MBMC matching network **200** is configured for providing an impedance match between the antenna **110** and the rectifier **120** with respect to multiple RF frequency bands that fall within the antenna's bandwidth, for purpose of enhancing or maximizing the transfer of RF power within multiple RF frequency bands from the antenna **110** to the rectifier **120**. More particularly, the MBMC matching network **200** is configured for providing an impedance match relative to multiple predetermined RF frequency bands (e.g., a plurality of RF frequency bands defined or set aside for a given purpose by a standards or regulatory agency/body) that fall within the bandwidth of the antenna **110**. As a result, the MBMC impedance matching network **200** enhances the amount of RF power across multiple RF frequency bands that can be coupled into the rectifier **120**.

[0060] In various embodiments, the MBMC matching network **200** includes a plurality of T-shaped transmission line matching structures, which are coupled in series between the input and the output of the MBMC matching network **200**. More particularly, in several embodiments, the MBMC matching network **200** includes an individual T-shaped transmission line matching structure corresponding to each individual RF frequency band for which the MBMC matching network **200** is intended to provide an impedance match. Consequently, an MBMC matching network **200** in accordance with an embodiment of the present disclosure can easily and exactly perform complex MBMC impedance transforming/matching in view of a given set of RF frequency bands and impedance matching requirements under consideration. Furthermore, MBMC matching networks **200** in accordance with embodiments of the present disclosure can realize frequency-dependent complex impedance matching at any two or more arbitrary frequencies. Several (e.g., two, three, or more) T-shaped transmission line matching structures can be cascaded (e.g., serially coupled to each other) in order to satisfy or solve MBMC impedance matching requirements. Such combinations of T-shaped transmission line matching structures provide highly flexible MBMC impedance matching solutions with respect to any given complex impedance matching situation at hand. The concept of these combinations is simple and surprisingly effective, which facilitates the applicability and extendibility of embodiments in accordance with the present disclosure to the use of closed-form equations for such cascaded MBMC impedance matching topologies.

[0061] At least one of the T-shaped transmission line matching structures is additionally coupled to electrical ground to provide a DC path. To further aid understanding, an MBMC matching network embodiment that is configured to provide matching for two RF frequency bands (e.g., the GSM-1800 and UTMS-2100 frequency bands), and which correspondingly includes two T-shaped transmission line matching structures, is described in detail below.

[0062] FIG. **5**A is a schematic illustration of a representative embodiment of an MBMC matching network **200** within an MBMC rectenna **100** in accordance with an embodiment of the present disclosure, where the MBMC matching network **200** is configured to provide impedance matching with respect to two RF frequency bands. Thus, this MBMC matching network **200** correspondingly includes a first **210** and a second **220** T-shaped transmission line matching structure. As indicated in FIG. **5**A, each T-shaped transmission line matching structure **210**, **220** includes three transmission lines. More specifically, the first T-shaped transmission line matching structure **210** includes (a) a first transmission line TL**1** that forms a first or left portion, branch, leg, or side of the first T-shaped transmission line matching structure **210**, and which provides an input of the MBMC matching network **200** that is coupled to the antenna **110**; (b) a second transmission line TL**2** coupled in series to the first transmission line TL**1** in a manner that forms a second or right portion, branch, leg, or side of the first T-shaped transmission line matching structure **210**, and which provides an output of the first T-shaped transmission line matching structure **210**; and (c) a third transmission line TL**3** coupled in parallel between the first transmission line TL**1** and the second transmission line TL**2**, which forms a third portion, branch, leg, or side of the first T-shaped transmission line matching structure. In an analogous manner, the second T-shaped transmission line matching structure **220** includes (d) a fourth transmission line TL**4** that forms a first or left portion, branch, leg, or side of the second T-shaped transmission line matching structure **220**, which provides an input of the second T-shaped transmission line matching structure **220** that is coupled to the second transmission line TL**2** of the first T-shaped transmission line matching structure **210**; (e) a fifth transmission line TL**5** coupled in series to the fourth transmission line TL**4** in a manner that forms a second or right portion, branch, leg, or side of the second T-shaped transmission line matching structure **220**, and which provides an output of the MBMC matching network **200**; and (f) a sixth transmission line TL**6** coupled in parallel between the fourth transmission line TL**4** and the fifth transmission line TL**5**, which forms a third portion, branch, leg, or side of the second T-shaped transmission line matching structure. Additionally, a third portion, branch, leg, or side of at least one T-shaped transmission line matching structure is coupled to electrical ground. For instance, the sixth transmission line TL**6**, that is, the third portion of the second T-shaped transmission line matching structure, can be coupled to electrical ground.

[0063] FIG. **5**A further indicates the width and length of each of the first through sixth transmission lines TL**1**-TL**6** for a representative implementation of the MBMC matching network **200** configured to provide impedance matching with respect to the GSM-1800 frequency band and the UTMS-2100 frequency band. FIG. **5**B is an image of an as-fabricated implementation the MBMC rectifier **102**, which includes this representative implementation of the MBMC matching network **200** having first through sixth transmission lines TL**1**-TL**6** fabricated with the dimensions indicated in FIG. **5**A; a conventional Schottky diode (e.g., an Avago HSMS-2852, C_j=0.18 pF, R_s=2512, Avago Technologies, Singapore) coupled to the output of the fifth transmission line TL**5**; and a DC pass filter **130** coupled to the Schottky diode. The DC pass filter **130** is implemented as a conventional stepped-impedance microstrip low pass filter. Each of the aforementioned elements was fabricated on a conventional circuit board, such as an RO4003 32 mil high frequency laminate circuit board (Rogers Corporation, Rogers, Conn. USA). Additionally, for this representative implementation, the resistive load **140** is a 6.4 kΩresistor.

[0064] To verify the frequency-power characteristics or performance of a rectenna **100** implemented as set forth above, single tone RF-to-DC power conversion efficiency (PCE) was tested using a signal generator (e.g., an Agilent E8257D, Agilent Technologies, Palo Alto, Calif. USA). FIG. **6** plots measured RF-to-DC PCE against frequency at different input RF power levels (−30 dBm to −18 dBM) for the representative implementation of the MBMC rectenna **100**. As indicated in FIG. **6**, a higher PCE is achieved at approximately 1.80-1.88 GHz and approximately 2.11-2.17 GHz than for other frequency bands, for all power levels, in accordance with intended objectives for the representative implementation of the MBMC rectenna **100**. Additionally, it will be readily understood by one having ordinary skill in the relevant art that when multiple or several channels in either of the 1.80-1.88 GHz band or the 2.11-2.17 GHZ band are activated, the RF power in such channels can be simultaneously converted to DC power at an enhanced or high PCE.

[0065] To further verify the PCE efficiency enhancement of this representative implementation of the MBMC rectenna **100**, two-tone RF-to-DC PCE performance was also examined using two Agilent E8257D signal generators and a ZFRSC-42 power splitter (Mini-Circuits, Brooklyn, N.Y. USA). FIG. **7** plots measured PCE against single and dual-tone input power for input signal frequencies of 1.83 GHz and 2.14 GHz, which are the approximate center frequencies of the 1.80-1.88 GHz and 2.11-2.17 GHz frequency bands. For purpose of simplicity, the input power for each of these tone frequencies was identical, across a predetermined range of input powers.

[0066] As indicated in FIG. **7**, RF-to-DC PCE is greater for dual tone input compared to single tone input across the tested range of input powers. Thus, the addition of RF input signals at different frequencies facilitates the generation of higher converted DC power and a higher PCE compared to single-tone RF input situations. FIG. **7** clearly indicates that the MBMC rectenna **100** can simultaneously harvest RF power that is dispersed among or across separate frequency bands and different channels within such frequency bands with an enhanced or considerably higher RF-to-DC PCE. Furthermore, when input power is approximately −30 dBm, which is expected to correspond to a relatively low ambient RF power level, the RF-to-DC PCE is only 5.29% and 4.79% for the individual 1.83 GHz and 2.14 GHz tones, respectively. However, the input of the corresponding two tone signal by way of simultaneous input of each of the 1.83 GHz and 2.14 GHz tones results in an RF-to-DC PCE of 11.65%, which surprisingly is more than twice the RF-to-DC PCE for either single tone input situation.

[0067] An additional representative implementation of the MBMC rectenna **100** was tested with respect to its ambient RF energy harvesting performance. In this additional representative implementation of the MBMC rectenna **100**, the antenna **110** was a wideband antenna **100**, rather than a dual band antenna. More specifically, in this additional representative implementation of the MBMC rectenna **100**, the MBMC matching network **200** was connected to the same wideband horn antenna utilized for generating the measurements of Table 1. The MBMC rectenna **100** was also positioned in the same modern urban environment as that used for generating the measurements of Table 1.

[0068] As indicated in Table 2, for this additional representative implementation of the MCMC rectenna **100**, received RF power was approximately −20 dBm, which is approximately 10 times greater than the −30 dBm relatively low ambient RF power level considered above for the dual tone situation. The output voltage of the rectifier **120** was approximately 120 mV. Therefore, the RF-to-DC PCE of this additional representative implementation of the MBMC rectenna **100** was approximately 22.5%, which greatly exceeds the RF-to-DC PCE measured for the above single tone situation, and which significantly exceeds the 11.65% RF-to-DC PCE measured for the above dual tone situation.

TABLE 2

Comparison of RF-to-dc PCE for single-tone, dual-tone, and multi-channel RF energy harvesting

Frequency Band	Received Power (dBm)	RF-to-DC PCE (%)
Single tone (1.83 GHz)	−30	5.29
Dual tone (1.83 & 2.14)	−30	11.65

TABLE 2-continued

Comparison of RF-to-dc PCE for single-tone, dual-tone, and multi-channel RF energy harvesting

Frequency Band	Received Power (dBm)	RF-to-DC PCE (%)
Urban area (multi-band multi-channel)	−20	22.5
Nearby transmission tower	−15	38.8

[0069] Finally, the additional representative implementation of the MBMC rectenna **100** was positioned near a commercial mobile telephony transmission tower, where the ambient RF energy would clearly be higher than in a modern urban area that is away or distant from the mobile transmission tower. When positioned near the mobile transmission tower, the measured RF received power varied between approximately −15 dBm and −20 dBm, in accordance with RF energy variations in multiple channels of the GSM-1800 and UMTS-2100 bands. Additionally, in this high ambient RF energy environment, the maximum DC voltage output by the rectifier **120** was approximately 280 mV. The RF-to-DC PCE for this additional implementation of the MBMC rectenna **100** in the high ambient RF energy environment can be derived according to the maximum input power (−15 dBm, −0.032 mW) to be approximately 38.8%.

[0070] Aspects of Representative Rectenna Rectifier Architectures

[0071] In addition or as an alternative to the foregoing, various embodiments in accordance with the present disclosure can enhance rectenna RF-to-DC PCE by way of a rectifier that can operate over an extended input power range. Depending upon embodiment details, an extended input power range rectifier can be, an adaptively reconfigurable rectifier, or a breakdown-protected rectifier, as described in detail hereafter.

[0072] Adaptively Reconfigurable Rectifier

[0073] FIG. **8**A is a schematic illustration of an adaptively reconfigurable rectenna or adaptive rectenna **300** based upon a first adaptively reconfigurable rectifier or first adaptive rectifier **302** in accordance with an embodiment of the present disclosure. Compared to the conventional high RF input power rectifier circuit shown in FIG. **2**B, the first adaptively reconfigurable rectifier **302** includes a transistor **310** coupled in parallel with the set of diodes D**2**. More particularly, in several embodiments the transistor **310** is a MOSFET having its gate coupled to ground; its drain and source coupled in parallel with the set of diodes D**2** (e.g., its drain can be coupled to the output of D**1**, and its source can be coupled between C**1** and L**1**.

[0074] Because the gate of the MOSFET **310** is maintained at ground potential, the MOSFET's gate-to-source voltage (V_{gs}) is equal to the inverse of the DC voltage output across load resistor R**1**. Consequently, the MOSFET **310** can serve as an adaptive switch that automatically selectively shunts the set of diodes D**2** based upon the DC voltage output across load resistor R**1**. More particularly, in a representative implementation, the MOSFET **310** is an n-channel depletion mode MOSFET, such as an NE3210S01 (NEC Corporation, Tokyo, Japan). When the input RF power is low, V_{gs} is near 0 Volts, and the MOSFET **310** is in the ON state, thereby shunting the set of diodes D**2**. Under such operating conditions, the first adaptively reconfigurable rectifier **302** behaves like the conventional low input power rectifier shown in FIG. **2**A. As input RF power increases, the DC voltage output across load resistor R_L increases, V_{gs} decreases, the MOSFET's channel resistance R_{ds} rises, and resistive loss within the MOSFET **310** increases. This resistive loss results in a slight adverse effect on RF-to-DC PCE as input RF power increases from a low to a moderate level (in contrast to the conventional low RF input power rectifier shown in FIG. **2**A).

[0075] As input RF power increases further, V_{gs} eventually reaches the cutoff voltage of the MOSFET **310**, and the MOSFET **310** is thus transitioned to its OFF state. Therefore, under higher/high input RF power conditions, the first adaptively reconfigurable rectifier **302** behaves like the conventional high input RF power rectifier shown in FIG. **2**B. Thus, the MOSFET **310** automatically reconfigures the first adaptively reconfigurable rectifier **302** to a more efficient rectifier topology (i.e., a high RF input power rectifier topology) under high input RF power conditions. Analogously, the MOSFET **310** automatically reconfigures the first adaptively reconfigurable rectifier **302** to a more efficient rectifier topology (i.e., a low input RF power rectifier topology) under low input RF power conditions. The first adaptively reconfigurable rectenna **300** can thus exhibit a greatly or dramatically increased input RF power operating range compared to either of the conventional rectennas of FIGS. **2**A and **2**B.

[0076] Notwithstanding the foregoing, within or across a given or predetermined input RF power range, V_{gs} is not sufficiently negative to completely turn off the MOSFET **310**, thereby resulting in an amount of resistive loss that can be non-negligible. This resistive loss problem can be solved by another adaptive rectifier topology, as described in detail hereafter.

[0077] FIG. **8**B is a schematic illustration of an adaptively reconfigurable rectenna or adaptive rectenna **350** based upon a second adaptively reconfigurable rectifier or second adaptive rectifier **352** in accordance with another embodiment of the present disclosure. In an embodiment, the second adaptively reconfigurable rectifier **352** includes two transistors **310**, **312** coupled in parallel across the set of diodes D**2**, rather than a single transistor **310** coupled in parallel across the set of diodes D**2**, in order to overcome the aforementioned resistive loss problem. In several embodiments, the two transistors **310**, **312** include a first and a second MOSFET **310**, **312** coupled or connected in series, where the gate of each MOSFET **310**, **312** is coupled to electrical ground. The source of the first MOSFET **310** is coupled between C**1** and L**1**, and the drain of the first MOSFET **310** is coupled to the source of the second MOSFET **312**. The source of the second MOSFET **312** is coupled to diode D**1**.

[0078] FIG. **8**C illustrates a circuit configuration of a representative implementation of the second adaptively reconfigurable rectenna **350** of FIG. **8**B, configured for operation at 100 MHz for purpose of example. In this representative implementation, diode D**1** is an HSMS-2852 diode (Avago Technologies, Singapore); the set of diodes D**2** is a set of four HSMS-2850 diodes, coupled pairwise between transmission line TL**7** in the manner shown; and the first and second MOSFETS **310**, **312** are NE2110S01 MOSFETS. (NEC Corporation, Tokyo, Japan). Additionally, C**1** is 5.1 pF; L**1** is 290 nH; and C**2** is 100 pF. Transmission lines TL**1** through TL**13** have widths (W) and lengths. (L) as follows, in millimeters: W**1**=2.4; L**1**=15; W**2**=W**3**=3.5; L**2**=L**3**=7.5; W**4**=2; L**4**=13; W**5**=W**6**=W**8**=W**9**=0.7; L**5**=L**6**=L**8**=L**9**=3; W**7**=0.7; L**7**=1.8; W**10**=2; L**10**=1; W**11**=3; L**11**=7; W**12**=5; L**12**=8; W**13**=4; and L**13**=5. Additionally, R_L=2.8 kΩ. FIG. **8**D is an image of the corresponding representative second adaptively reconfigurable rectifier **352**, as fabricated on a 31 mil Rogers RT/duroid 5880 substrate having a dielectric constant of 2.2 and a loss tangent of 0.0012. One having ordinary skill in the relevant art will understand that depending upon embodiment and/or implementation details, diode D**1** can be a set of diodes (i.e., one or more diodes); and/or the set of diodes D**2** can be a single diode rather than multiple diodes.

[0079] For comparison purposes, simulations of the RF-to-DC PCE versus input RF power for the conventional low RF input power rectifier shown in FIG. **2**A, the conventional high RF input power rectifier shown in FIG. **2**B, the first adaptively reconfigurable rectifier **302** shown in FIG. **8**A, and the second adaptively reconfigurable rectifier **352** of FIG. **8**B were performed using diode D**1**, the set of diodes D**2**, capacitors C**1** and C**2**, inductance L**1**, and load resistance R_L defined as given above. Each such simulation corresponded to an operating frequency of 100 MHz, for purpose of example.

[0080] FIG. **9**A is a graph showing RF-to-DC PCE simulation results for (a) the conventional low RF input power rectifier shown in FIG. **2**A; (b) the conventional high RF input power rectifier shown in FIG. **2**B; (c) the first adaptively reconfigurable rectifier **302** shown in FIG. **8**A; and (d) the second adaptively reconfigurable rectifier **352** shown in FIG. **8**B. From FIG. **9**A, one can readily note the following:

> **[0081]** (a) With respect to the Conventional low RF input power rectifier shown in FIG. **2**A, it is clear that its RF-to-DC PCE increases with increasing input RF power until reaching a maximum of approximately 85% of input RF power at approximately 0.3 dBm. When the input RF power exceeds this level, the RF-to-DC PCE of the conventional rectifier shown in FIG. **2**A decreases rapidly, since the voltage swing across D**1** exceeds D**1**'s breakdown voltage. Thus, the conventional low RF input power rectifier shown in FIG. **2**A is suitable only for low input RF power situations, and is unsuitable for high input RF power situations.

> **[0082]** (b) With respect to the conventional high RF input power rectifier shown in FIG. **2**B, the RF-to-DC PCE at low RF input powers is less than that for the conventional low RF input power rectifier shown in FIG. **2**A. For instance, when the input RF power is less than about −5 dBm, the RF-to-DC PCE of the conventional high RF input power rectifier remains below approximately 30%. However, the RF-to-DC PCE at high RF input powers is much better than that for the conventional low RF input power rectifier shown in FIG. **2**A, reaching a peak of approximately 82% at about 19 dBm input RF power. Thus, the conventional rectifier shown FIG. **2**B is suitable only for high input RF power situations.

[0083] (c) With respect to the first adaptively reconfigurable rectifier **302** shown in FIG. **8**A, its RF-to-DC PCE generally matches that for the conventional rectifier shown in FIG. **2**A for input RF power less than −15 dBm. As input RF power increases from approximately −15 dBm to approximately 0 dBm, the RF-to-DC PCE of the first adaptively reconfigurable rectifier **302** is slightly reduced compared to that of the conventional low RF input power rectifier because of the aforementioned resistive loss due to the MOSFET **310**. When the input RF power exceeds approximately 10 dBm, V_{gs} reaches the cutoff voltage of the MOSFET **310**, thereby switching the MOSFET **310** to the OFF state. Under such high RF input power conditions, the first adaptively reconfigurable rectifier **302** operates in a manner that is generally similar or analogous to that of the conventional high RF input power rectifier of FIG. **2**B.

> **[0084]** (d) With respect to the second adaptively reconfigurable rectifier **352**, FIG. **9** indicates that the second adaptively reconfigurable rectifier **352** achieves a better OFF state than the first adaptively reconfigurable rectifier **302** across a range of input RF power between approximately 3 dBm and 20 dBm. Thus, the second adaptively reconfigurable rectifier **352** provides significantly enhanced RF-to-DC PCE across a wide input RF power range, for instance, from approximately 3 dBm to 20 dBm, compared to the other rectifiers considered in this simulation.

[0085] In addition to the foregoing, the RF-to-DC PCE of the representative implementation of the second adaptively reconfigurable rectifier **352** shown in FIGS. **8**C-**8**D was measured versus input RF power. More particularly, input RF power and DC voltage output across the resistive load R_L were simultaneously measured, and the RF-to-DC PCE was calculated in accordance with the following equation:

$$\eta=(V_L)^2/R_L\times(1/P_{in})\times100 \quad (1)$$

in a manner readily understood by those having ordinary skill in the relevant art.

[0086] FIG. **9**B is a graph showing measured versus simulated RF-to-DC PCE, as well as measured versus simulated output voltage, as a function of input RF power for the aforementioned representative implementation of the second adaptively reconfigurable rectifier **352**. The measured and simulated results exhibit good agreement with each other. FIG. **9**B indicates that an RF-to-DC PCE exceeding 50% can be achieved across an extended or enhanced input RF power range, from approximately −14 dBm to 21 dBm. Additionally, an RF-to-DC PCE greater than equal to approximately 75% can be reached for input RF powers between approximately 7 dBm and 14 dBm. Also, a highest DC output voltage of about 14.9V can be reached when input RF power approximately equals 23 dBm. The measured results shown in FIG. **9**B clearly indicate that the second adaptively reconfigurable rectifier **352** is suitable for WPT and/or RF energy harvesting applications in which a wide operating input RF power range is desired or required.

[0087] Further to the foregoing, an adaptively reconfigurable rectifier can include more than two transistors (e.g., more than two MOSFETs) coupled in parallel with the set of diodes D**2**. For instance, an adaptively reconfigurable rectifier can include three, four, or more MOSFETs coupled in parallel with the set of diodes D**2**, where such MOSFETs are stacked in series. FIG. **9**C is a graph showing simulated RF-to-DC PCE versus input RF power corresponding to FIG. **9**A, but which also includes simulation results for an adaptively reconfigurable rectifier having three MOSFETs coupled across/in parallel with the set of diodes D**2**, as well as an adaptively reconfigurable rectifier having four MOSFETs coupled across/in parallel with the set of diodes D**2**. More particularly, FIG. **9**C illustrates simulated RF-to-DC PCE versus input RF power for (a) the conventional low RF input power rectifier of FIG. **2**A (indicated as "Eff(a)" in FIG. **9**C); (b) the conventional high RF input power rectifier of FIG. **2**B (indicated as "Eff(b)" in FIG. **9**C); (c) the first adaptively reconfigurable rectifier **302** of FIG. **8**A (indicated as "Eff(c)" in FIG. **9**C); and (d) three versions of the second adaptively reconfigurable rectifier **352** of FIG. **8**B, namely, (i) a version with N=2 MOSFETs **310**, **312**; a version with N=3 MOSFETs; and (iii) a version with N=4 MOSFETs (respectively indicated as "Eff(d) N=2", "Eff(d) N=3", and "Eff(d) N=4" in FIG. **9**C), where such MOSFETs in each version are serially stacked and coupled in parallel with diode D**1**. FIG. **9**C indicates that as the number of serially stacked MOSFETs increases, the RF-to-DC PCE tends to be higher in the high RF input power region, and lower in the low RF input power region.

[0088] Still further to the foregoing, FIG. **9**D is a graph of simulated RF-to-DC PCE versus RF input power for different values of the load resistance R_L for the second adaptively reconfigurable rectifier **352**. FIG. **9**D indicates that as load resistance R_L increases, the RF-to-DC PCE tends to be higher in the low RF input power region, and lower in the high RF input power region.

[0089] Thus, there can be certain tradeoffs in terms of RF-to-DC PCE performance with respect to the number of MOSFETs stacked in series, and/or load resistance R_L. Furthermore, the threshold voltage of the MOSFET(s) should be selected such that under high RF input power conditions, the instantaneous V_{gs} will turn the FET(s) off when the reverse bias across diode D**1** approaches D**1**'s breakdown voltage, as will be readily understood by one having ordinary skill in the relevant art.

[0090] Breakdown-Protected Rectifier

[0091] FIG. **10**A is a schematic illustration of a breakdown-protected rectenna **400** based upon a breakdown-protected rectifier **402** in accordance with an embodiment of the present disclosure. In various embodiments, the breakdown-protected rectifier **402** includes a transistor-protected diode structure **410** that includes at least one diode coupled to a transistor in a manner that protects the diode from direct exposure to negative voltages that would ordinarily cause the diode to break down in the absence of the transistor. For an embodiment in which the transistor-protected diode structure **410** includes a single diode D**1** and a single transistor, a first or control terminal of a transistor is coupled to the anode of diode D**1**; a second transistor terminal is coupled in series to the output or cathode of diode D**1**; and a third transistor terminal is coupled to a load resistance R_L. As a result of such transistor coupling, a negative voltage having a magnitude equal to or greater than the reverse breakdown voltage of diode D**1**, to which diode D**1** would normally be directly exposed in the absence of the transistor, is instead expressed across the combination of the transistor and diode D**1**. The transistor thus protects diode D**1** from direct exposure to a negative voltage having a magnitude that exceeds diode D**1**'s breakdown voltage, until the transistor itself is exposed to a negative voltage between its control terminal and its third terminal that causes junction breakdown within transistor itself.

[0092] FIG. **11**A is a schematic illustration of a first transistor-protected diode structure **410***a* in accordance with an embodiment of the present disclosure. In several embodiments, the first transistor-protected diode structure **410***a* includes a MOSFET **420** having a gate coupled to the input or anode of diode D**1**; a source coupled to the output or cathode of diode D**1**; and a drain couplable to a load resistance R_L. In a representative implementation, diode D**1** can be a Schottky diode, such as an Avago HSMS-2852, having a forward threshold voltage of approximately 150 mV and a reverse breakdown voltage of approximately −3.8 V; and the MOSFET **420** can be an n-channel depletion mode MOSFET, such as a BF998 MOSFET (NXP Semiconductors, Eindhoven, NL), which has a threshold voltage V_{th} of approximately −0.8V. When the combination of diode D**1** and the MOSFET **420** is forward biased ($V_a>V_b$), the MOSFET is in the ON state because V_{gs} is positive, and the combination behaves like a single diode having approximately the same built-in voltage as diode D**1** by itself. One having ordinary skill in the relevant art will understand that there will be a small amount of resistive loss in the MOSFET **420** under such operating conditions.

[0093] When the combination of diode D**1** and the MOSFET **420** is reverse biased ($V_a<V_b$) and V_{ab}, is negative but larger than the breakdown voltage of diode D**1**, V_{gs} is smaller than the MOSFET's threshold voltage. Therefore, MOSFET **420** transitions to an OFF state before diode D**1** breaks down. Consequently, even if the overall bias voltage V_{ab} across the combination of diode D**1** and the MOSFET **420** is beyond the breakdown voltage of diode D**1**, the actual voltage across diode D**1** remains smaller that its breakdown voltage because the major portion of the voltage is sustained between the drain and the source of the MOSFET **420**. When the overall bias voltage V_{ab} is beyond the maximum gate-to-drain voltage V_{gd} that the MOSFET **420** can withstand, the MOSFET **420** will break down.

[0094] FIG. **12** is a graph illustrating the I-V characteristics of each of diode D**1** and the first transistor-protected diode structure **410***a*, in accordance with the aforementioned representative implementations thereof. As clearly indicated in FIG. **12**, the first transistor-protected diode structure **410***a* exhibits a breakdown voltage having a magnitude that is dramatically greater than that of diode D**1** alone. As a result, incorporation of a transistor-protected diode structure **420** into a rectifier can be expected to significantly or dramatically enhance the rectifier's RF-to-DC PCE.

[0095] FIG. **13** is a graph illustrating simulated RF-to-DC PCE versus input RF power level for the rectifier shown in FIG. **2**C as well as the breakdown-protected rectifier **402** of FIG. **10**A at a representative operating frequency of 50 MHz. Each such circuit utilizes C**1**=8 pF, L**1**=750 nH, C**2**=10 pF, and R_L=6.0 kΩ. Diode D**1** and the MOSFET **420** are defined in accordance with the representative implementations thereof indicated above. The conventional rectifier of FIG. **2**C provides an RF-to-DC PCE above 50% for input RF power levels between approximately −20.5 to −0.5 dBm. For higher input RF power levels, the RF-to-DC PCE of the conventional rectifier of FIG. **2**C degrades sharply because the voltage swings across diode D**1** exceed its breakdown voltage. Thus, the conventional rectifier of FIG. **2**C is suitable only for low RF input power conditions.

[0096] As shown in FIG. **13**, the RF-to-DC PCE of the breakdown-protected rectifier **402** of FIG. **10**A is slightly less than that of the conventional rectifier of FIG. **2**C for input RF power between approximately −25 dBm to −2.5 dBm, which can be attributed to the small resistive loss associated with the MOSFET **420**. However, the RF-to-DC PCE of the breakdown-protected rectifier **402** remains above 50% for input RF power levels from approximately −18.5 to 17.5 dBm, clearly indicating that the operating input RF power range of the breakdown-protected rectifier **402** is significantly extended compared to that of the conventional rectifier of FIG. **2**A.

[0097] FIG. **10**B is a schematic illustration of a representative implementation of the breakdown-protected rectifier **402** of FIG. **10**A. In this representative implementations, the widths and lengths of transmission lines TL**1** through TL**13** in millimeters are as follows: W**1**=2.4; L**1**=5.0; W**2**=W**3** W**4**=W**5**=W**6**=W**7**=1.8; L**2**=2.9; L**3**=4.8; L**4**=4.0; L**5**=−9.25; L**6**=1.2; L**7**=25.6; W**8**=3; L**8**=2; W**9**=1; L**9**=1.8; W**10**=1.0; L**10**=4.2; W**11**=W**13**=1.8; W**12**=3; L**11**=3.9; L**12**=4.9; and L**13**=4.0. As above, C**1**=8 pF; L**1**=750 nH; C**2**=100 pF, and RL=6.0 kΩ. This representative implementation of the breakdown-protected rectifier **400** was fabricated on a 31 mil thick Rogers RT/duroid 5880 substrate, which has a dielectric constant of 2.2 and a loss tangent of 0.0012. FIG. **10**C is an image of the as-fabricated representative implementation of the breakdown-protected rectifier **402**.

[0098] FIG. **14** is a graph showing measured versus simulated RF-to-DC PCE, as well as measured versus simulated output voltage, as a function of input RF power for the aforementioned representative implementation of the breakdown-protected rectifier **402** of FIGS. **10**B and **10**C. Measured and simulated results exhibit good agreement with each other. The measured RF-to-DC PCE was greater than 50% across an input RF power range from approximately −13.5 dBm to 16.7 dBm. Additionally, the highest DC output voltage reached approximately 11.9V for input RF power of about 17.6 dBm. Thus, the breakdown-protected rectifier **402** can enhance RF-to-DC PCE in WPT and/or ambient RF energy harvesting applications in which a wide operating RF input power range is desired or required.

[0099] In addition to the first transistor-protected diode structure **410***a*, a variety of other transistor-protected diode structures **410** exist. For instance, FIGS. **11**B-**11**H are schematic illustrations of a second through a seventh transistor-protected diode structure **410***b-h*, which can be incorporated into a rectifier to form a breakdown-protected rectifier **400** in accordance with an embodiment of the present disclosure. As indicated in FIG. **11**B, a second diode D**2** can be coupled such that it is coupled in parallel with the source and drain of the MOSFET **420**. More particularly, the anode of diode D**2** can be coupled to the cathode of diode D**1**, and hence to the source of the MOSFET **420**; and the cathode of diode D**2** is coupled to the drain of the MOSFET **420**, and hence to a load resistor R_L. The presence of diode D**2** can facilitate the reduction of minimization of forward resistive losses within the MOSFET **420** under forward biasing conditions, in a manner readily understood by one having ordinary skill in the relevant art.

[0100] As indicated in FIGS. **11**C and **11**D, as well as FIGS. **11**E-**11**H, circuit elements can be coupled to the gate of the MOSFET **420** to distribute reverse voltages across the gate-to-drain junction of the MOSFET **420** in addition to one or more types of circuit elements under consideration, thereby further increasing the overall magnitude of the breakdown voltage for the transistor-protected diode structure **410** under consideration relative to the breakdown voltage of the first transistor-protected diode structure **410***a* of FIG. **11**A. FIGS. **11**E-**11**H illustrate manners in which particular individual transistor-protected diode structures **410** can be cascaded or iteratively coupled to achieve breakdown voltage enhancement compared to the first transistor-protected diode structure **410***a*.

[0101] Further Representative Rectenna Designs

[0102] Rectennas in accordance with embodiments of the present disclosure can include an MBMC matching network **200**, either alone or in combination with either of an adaptively reconfigurable rectifier **300**, **350** or a transistor-protected rectifier **400**. For instance, FIG. **15**A illustrates a rectenna **500** having each of an MBMC matching network **200** and a second adaptively reconfigurable rectifier **352** in accordance with an embodiment of the present disclosure. FIG. **15**B illustrates a rectenna **550** having each of an MBMC matching network **200** and a breakdown-protected rectifier **402** in accordance with an embodiment of the present disclosure.

[0103] Further Performance Comparisons

[0104] FIG. **16** is a graph illustrating simulated RF-to-DC PCE versus input RF power for representative implementations of each of (a) the conventional low input RF power rectifier of FIG. **2**A; (b) the MBMC rectifier **102** of FIG. **3**; (c) the second adaptively reconfigurable rectifier **352** shown in FIG. **8**B; (d) the MBMC matching network **200** coupled to the second adaptively reconfigurable rectifier **352**, in a manner shown in FIG. **15**A; (e) the breakdown-protected rectifier **402** of FIG. **10**A; and (f) the MBMC matching network **200** coupled to the breakdown-protected rectifier **402**, in a manner shown in FIG. **15**B.

[0105] As indicated in FIG. **16**, each of the rectifiers corresponding to simulation results (b) through (f) exhibit enhanced RF-to-DC PCE compared to the conventional low input RF power rectifier shown in FIG. **2**A. Furthermore, each of the second adaptively reconfigurable rectifier **352**, the breakdown-protected rectifier **402**, and the combination of the MBMC matching network **200** coupled with either of the second adaptively reconfigurable rectifier **352** or the breakdown-protected rectifier **402** exhibit a significantly or dramatically enhanced or extended input RF power operating range compared to the conventional low input RF power rectifier shown in FIG. **2**A.

[0106] The main function of a MBMC network **200** within an MBMC rectifier **102** in accordance with an embodiment of the present disclosure is to collect more ambient RF power in order to increase the input RF power level so as to increase the overall RF-to-DC PCE of a WPT or an ambient RF energy harvesting system, apparatus, device, or circuit. On the other hand, an adaptively reconfigurable rectifier **302**, **352** or a breakdown-protected rectifier **402** in accordance with an embodiment of the present disclosure is mainly used to enhance the breakdown voltage of a rectifier's semiconductor diode component(s), to thereby significantly enhance the input RF power operating range of the rectifier.

[0107] The combination of an MBMC matching network **200** in accordance with an embodiment of the present disclosure with an embodiment of either of an adaptively reconfigurable rectifier **302**, **352** (e.g., as shown in FIG. **15**A) or a breakdown-protected rectifier **402** (e.g., as shown in FIG. **15**B) provides an enhanced or higher RF-to-DC PCE and much higher breakdown power performance when compared with a conventional low RF input power rectifier or a rectifier that includes the MBMC matching network **200**, but which excludes adaptively reconfigurable circuit elements or transistor-protected diodes, respectively, in accordance with embodiments described herein.

[0108] An adaptively reconfigurable rectifier **302**,**352** or a breakdown protected rectifier **402** that is coupled to or which includes an MBMC matching network **200** can collect more RF power than a rectifier configured to receive RF power within a single RF frequency band, and can have a higher RF-to-DC PCE compared with an adaptively reconfigurable rectifier **302**,**352** or a breakdown protected rectifier **402** that is not coupled to or which excludes an MBMC matching network **200**. However, an adaptively reconfigurable rectifier **302**, **352** or a breakdown-protected rectifier **402** that is coupled to or which an MBMC matching network **200** will reach its breakdown power level at a lower overall input RF power level than an adaptively reconfigurable rectifier **302**, **352** or a breakdown-protected rectifier **402** that is not coupled to or which excludes an MBMC matching network **200**, due to greater RF energy collection or harvesting by the MBMC matching network **200** under the same RF environmental conditions.

[0109] Wireless Network Considerations

[0110] A rectenna or rectifier in accordance with an embodiment of the present disclosure (e.g., essentially any rectenna that includes an MBMC matching network **200** and/or one of an adaptively reconfigurable rectifier **350**, **352** or a breakdown-protected rectifier **400**) can be utilized in or form a portion of a wireless network configured for transmitting/receiving (TX/RX) electromagnetic signals. The use of a particular rectenna or rectifier structure or topology in accordance with an embodiment of the present disclosure within a given wireless network, and the implementation thereof, can be based upon a wireless network architecture or application, input RF power operating range, a set of RF frequency bands under, and/or particular RF-to-DC PCE objectives/requirements under consideration.

[0111] FIGS. **17**A-**17**H are block diagrams illustrating representative types of wireless networks **600** in which a set of rectennas (e.g., including one or more MBMC rectennas **100**, adaptively reconfigurable rectennas **300**, **350**, and/or breakdown-protected rectennas **400**) in accordance with one or more embodiments of the present disclosure can be deployed. More particularly, FIG. **17**A illustrates a one-to-one TX/RX wireless network **600***a* in which a single TX stage **610** wirelessly transfers signals to a single RX stage **630**. The RX stage **630** is coupled to a set of devices **650** such as a set of sensors. In a WPT application, the set of devices **650** can receive power output by the RX stage **630**, which converts RF signals received from the TX stage **610** into DC signals in a manner identical, essentially identical, or analogous to that described herein (e.g., by way of an MBMC rectenna **100**, an adaptively reconfigurable rectenna **300**, **350**, or a breakdown-protected rectenna **400**), in a manner readily understood by one having ordinary skill in the relevant art.

[0112] FIG. **17**B illustrates a TX/RX wireless network **600***b* including one "repeater"/"amplification" stage **620** disposed between a TX stage **610** and an RX stage **630**, where; the RX stage **630** is coupled to a set of devices **650** (e.g., a set of sensors) as above. The TX stage **610** can wirelessly transfer RF signals to the repeater/amplification stage **620**, which can further wirelessly transfer RF signals to the RX stage **630**. The repeater/amplification stage **620** includes an adjunct RX stage **622** configured for receiving RF signals from the TX stage **610**; and an adjunct TX stage **624** configured for transmitting RF signals to the RX stage **630**. The presence of the repeater/amplification stage **620** can extend the physical range across which the TX stage **610** and the RX stage **630** are separable/separated, and/or enhance the likelihood of reliable wireless signal reception by the RX stage **630**. One or both of the repeater/amplification stage **620** and the RX stage **630** can receive power by way of WPT and/or ambient RF energy harvesting (e.g., by way of an MBMC rectenna **100**, an adaptively reconfigurable rectenna **300**, **350**, a breakdown-protected rectenna **400**, or a combination of an MBMC rectenna **100** with one of an adaptively reconfigurable rectenna **300**, **350** or a breakdown-protected rectenna **400**), depending upon embodiment details. Furthermore, depending upon embodiment details, the RX stage **630** and the adjunct RX stage **622** can have identical, similar, or different structures or topologies.

[0113] In a manner analogous to that shown in FIG. **17**B, FIG. **17**C illustrates a TX/RX wireless network **600***c* including multiple repeater/amplification **620***a,b* stages disposed between a TX stage **610** and an RX stage **630**. Each repeater/amplification stage **620** includes an adjunct RX stage **622** and an adjunct TX stage **624**, in a manner analogous to that described above. The RX stage **630** and/or one or more of the repeater/amplification stages **620***a,b* can receive power by way of WPT and/or ambient RF energy harvesting (e.g., by way of an MBMC rectenna **100**, an adaptively reconfigurable rectenna **300**, **350**, a breakdown-protected rectenna **400**, or a combination of an MBMC rectenna **100** with one of an adaptively reconfigurable rectenna **300**, **350** or a breakdown-protected rectenna **400**), depending upon embodiment details. Here again, the presence of each repeater/amplification stage **620***a,b* can extend the physical range across which the TX stage **610** and the RX stage **630** are separable/separated, and/or enhance the likelihood of reliable wireless signal reception by the RX stage **630**. Such a wireless network **600***c* can be scaled to include N repeater/amplification stages **620**, in a manner understood by one having ordinary skill in the relevant art. Depending upon embodiment details, the RX stage **630** and one or more adjunct RX stages **622** can have identical, similar, or different structures or topologies.

[0114] FIGS. **17**D-**17**H illustrate further wireless network architectures or configurations **600***d-h* in which one or more RX stages **630** and/or one or more repeater/amplification stages **620** can employ an MBMC rectenna **100**, an adaptively reconfigurable rectenna **300**, **350**, or a breakdown-protected rectenna **400**, in a manner analogous to that described above. In general, one or more rectenna embodiments in accordance with the present disclosure can be utilized in or form portions of an m-to-p TX/RX network, where m indicates the number of TX stages **610** and p indicates the number of RX stages **630** present in the network. Each of m and p can be one or more (e.g., m can equal 1, indicating a single TX stage **610**; and p can equal 1, several, dozens, hundreds, thousands, or more, indicating the presence of one to possibly hundreds, thousands, or more RX stages **630**). Similarly, one or more rectenna embodiments in accordance with the present disclosure can be utilized in or form portions of an m-to-n-to-p TX/repeater-amplification/RX network, where m indicates the number of TX stages **610**; n indicates the number of repeater/amplification stages **620**; and p indicates the number of RX stages **630** in the network. Each of m, n, and p can be one or more, in a manner identical, essentially identical, or analogous to that previously indicated.

[0115] Thus, in view of the foregoing, one or more rectennas in accordance with various embodiments of the present disclosure can be utilized in or form portions of essentially any type of wireless network organized in accordance with essentially any type of wireless network topology, wherein electromagnetic signals are received and rectified. Furthermore, one or more RX stages **630** and/or one or more repeater/amplification stages **620** within such wireless networks can receive power by way of WPT and/or ambient RF energy harvesting, such as by way of an MBMC rectenna **100**, an adaptively reconfigurable rectenna **300**, **350**, or a breakdown-protected rectenna **400** in a manner identical, analogous, or generally analogous to that described above, depending upon embodiment details.

[0116] Aspects of particular embodiments of the present disclosure address at least one aspect, problem, limitation, and/or disadvantage associated with existing rectenna and/or rectifier circuit elements, circuits, or techniques. While features, aspects, and/or advantages associated with certain embodiments have been described in the disclosure, other Embodiments may also exhibit such features, aspects, and/or advantages, and not all embodiments need necessarily exhibit such features, aspects, and/or advantages to fall within the scope of the disclosure. It will be appreciated by a person of ordinary skill in the art that several of the above-disclosed systems, components, processes, or alternatives thereof, may be desirably combined into other different systems, components, processes, and/or applications. In addition, various modifications, alterations, and/or improvements may be made to various embodiments that are disclosed by a person of ordinary skill in the art within the scope and spirit of the present disclosure.

1. A circuit configured for receiving RF energy distributed in multiple RF frequency bands, the circuit including a multi-band multi-channel (MBMC) matching network, the MBMC matching network comprising:

a plurality of T-shaped transmission line matching structures, each T-shaped transmission line matching structure coupled in series to another T-shaped transmission line matching structure,

wherein each T-shaped transmission line matching structure includes a first portion, a second portion, and a third portion coupled between the first portion and the second portion,

wherein the first portion of a first T-shaped transmission line matching structure within the plurality of T-shaped transmission line structures forms an input of the MBMC matching network, the second portion of a second T-shaped transmission line matching structure within the plurality of T-shaped transmission line matching structures forms an output of the MBMC matching network, and the third portion of at least one T-shaped transmission line matching structure within the plurality of T-shaped transmission line matching structures is couplable to electrical ground.

2. The circuit of claim **1**, wherein each individual T-shaped transmission line matching structure within the MBMC matching network is configured for providing an impedance match corresponding to RF frequencies within a particular RF frequency band.

3. The circuit of claim **1**, wherein the circuit includes a rectenna comprising:

an antenna coupled to the input of the MBMC Matching network; and

a rectifier coupled to the output of the MBMC matching network.

4. The circuit of claim **3**, wherein the circuit forms a portion of a wireless power transmission (WPT) system or a portion of an ambient RF energy harvesting system.

5. The circuit of claim **3**, wherein the rectifier comprises one of:

an adaptively reconfigurable rectifier having a low input RF power rectifying portion, a high input RF power rectifying portion, and a set of transistors coupled to one of the high input RF power rectifying portion the low input RF power rectifying portion, the set of transistors configured for automatically transitioning the adaptively reconfigurable rectifier between a low input RF input power operating configuration and a high input RF power operating configuration based upon input RF power level; and

a breakdown-protected rectifier having at least transistor-protected diode structure, the transistor-protected diode structure comprising at least one diode coupled to a transistor in a manner that protects the diode from direct exposure to negative voltages that would ordinarily cause the diode to break down in the absence of the transistor.

6. A circuit configured for rectifying signals, comprising one of:

an adaptively reconfigurable rectifier having a low input power rectifying portion, a high input power rectifying portion, and a set of transistors coupled to one of the high input power rectifying portion the low input power rectifying portion, the set of transistors configured for selectively and automatically transitioning the adaptively reconfigurable rectifier between a low input power operating configuration and a high input RF power operating configuration in a manner correlated with a power level of a signal input to the circuit; and

a breakdown-protected rectifier having at least one transistor-protected diode structure, the at least one transistor-protected diode structure comprising a first diode coupled to a transistor in a manner that protects the first diode from direct exposure to negative voltages that would ordinarily cause the diode to break down in the absence of the transistor.

7. The circuit of claim **6**, wherein the low input power portion and the high input power portion of the adaptively reconfigurable rectifier are coupled in series.

8. The circuit of claim **7**, wherein the set of transistors of the adaptively reconfigurable is coupled in parallel with the high input power portion.

9. The circuit of claim **6**, wherein a control terminal of each transistor within the set of transistors of the adaptively reconfigurable rectifier is coupled to electrical ground.

10. The circuit of claim **6**, wherein the set of transistors of the adaptively reconfigurable rectifier includes a plurality of transistors coupled to each other in series.

11. The circuit of claim **6**, wherein each transistor within the set of transistors is a Field Effect Transistor (FET).

12. The circuit of claim **6**, wherein the low input power rectifying portion of the adaptively reconfigurable rectifier comprises a first set of diodes, and the high input power rectifying portion comprises a second set of diodes.

13. The circuit of claim **12**, wherein at least one of the first set of diodes and the second set of diodes includes a plurality of diodes.

14. The circuit of claim **6**, wherein the breakdown-protected rectifier comprises a first transistor-protected diode structure including a first diode and a transistor, and wherein the transistor includes a control terminal coupled to the anode of the first diode, a first terminal coupled to the cathode of the, first diode, and a second terminal couplable to circuitry external to the transistor-protected diode structure.

15. The circuit of claim **14**, wherein the anode of the first diode is coupled to an input of the breakdown-protected rectifier and is configured to receive an alternating current (AC) signal, and wherein the second terminal of the transistor is coupled to an output of the breakdown-protected rectifier.

16. The circuit of claim **14**, wherein the transistor-protected diode structure further includes a second diode coupled in parallel with the second terminal and the third terminal of the transistor, such that the anode of the second diode is coupled to the cathode of the first diode.

17. The circuit of claim **14**, wherein the transistor-protected diode structure further includes a second diode having its anode coupled to the anode of the first diode, and its cathode coupled to the control terminal of the transistor.

18. The circuit of claim **14**, wherein the breakdown-protected rectifier comprises the first transistor-protected diode structure combined with a second transistor-protected diode structure coupled in a cascaded manner to the first transistor-protected diode structure, such that a negative voltage across the combination of the first and second transistor-protected diode structures is distributed across the transistor of the first transistor-protected diode structure and a transistor of the second transistor-protected diode structure.

19. The circuit of claim **18**, wherein the second transistor-protected diode structure comprises a first diode and a transistor having a control input, a first terminal, and a second terminal, and wherein the anode of the first diode of the second transistor-protected diode structure is coupled to the anode of the first diode of the first transistor-protected diode structure, the cathode of the first diode of the second transistor-protected diode structure is coupled to the second terminal of the transistor of the second diode-protected transistor structure, and the third terminal of the transistor of the second diode-protected transistor structure is coupled to the control input of the transistor of the first diode-protected transistor structure.

20. A wireless network comprising:

a transmission (TX) stage configured for wirelessly transmitting electromagnetic signals; and

a reception (RX) stage configured for receiving electromagnetic signals transmitted by the TX stage, the RX stage comprising one of:

(a) a multi-band multi-channel (MBMC) matching network comprising: a plurality of T-shaped, transmission line matching structures, each T-shaped transmission line matching structure coupled in series to another T-shaped transmission line matching structure,

wherein each T-shaped transmission line matching structure includes a first portion, a second portion, and a third portion coupled between the first portion and the second portion,

wherein the first portion of a first T-shaped transmission line matching structure within the plurality of T-shaped transmission line structures forms an input of the MBMC matching network, the second portion of a second T-shaped transmission line matching structure within the plurality of T-shaped transmission line matching structures forms an output of the MBMC matching network, and the third portion of at least one T-shaped transmission line matching structure within the plurality of T-shaped transmission line matching structures is couplable to electrical ground;

(b) an adaptively reconfigurable rectifier having a low input power rectifying portion, a high input power rectifying portion, and a set of transistors coupled to one of the high input power rectifying portion the low input power rectifying portion, the set of transistors configured for selectively and automatically transitioning the adaptively reconfigurable rectifier between a low input power operating configuration and a high input RF power operating configuration in a manner correlated with a power level of a signal input to the RX stage; and

(c) a breakdown-protected rectifier having at least one transistor-protected diode structure, the at least one transistor-protected diode structure comprising a first diode coupled to a transistor in a manner that protects the first diode from direct exposure to negative voltages that would ordinarily cause the diode to break down in the absence of the transistor.

21. The wireless network of claim **20**, wherein the RX stage includes the MBMC matching network and one of the adaptively reconfigurable rectifier and the breakdown-protected rectifier.

22. The wireless network of claim **20**, further comprising at least one repeater/amplification stage configured to receive electromagnetic signals from the. TX stage and transmit electromagnetic signals to the RX stage, the at least one repeater/amplification stage comprising one of:

(a) a multi-band multi-channel (MBMC) matching network comprising:

a plurality of T-shaped transmission line matching structures, each T-shaped transmission line matching structure coupled in series to another T-shaped transmission line matching structure,

wherein each T-shaped transmission line matching structure includes a first portion, a second portion, and a third portion coupled between the first portion and the second portion,

wherein the first portion of a first T-shaped transmission line matching structure within the plurality of T-shaped transmission line structures forms an input of the MBMC matching network, the second portion of a second T-shaped transmission line matching structure within the plurality of T-shaped transmission line matching structures forms an output of the MBMC matching network, and the third portion of at least one T-shaped transmission line matching structure within the plurality of T-shaped transmission line matching structures is couplable to electrical ground;

(b) an adaptively reconfigurable rectifier having a low input power rectifying portion, a high input power rectifying portion, and a set of transistors coupled to one of the high input power rectifying portion the low input power rectifying portion, the set of transistors configured for selectively and automatically transitioning the adaptively reconfigurable rectifier between a low input power operating configuration and a high input RF power operating configuration in a manner correlated with a power level of a signal input to the RX stage; and

(c) a breakdown-protected rectifier having at least one transistor-protected diode structure, the at least one transistor-protected diode structure comprising a first diode coupled to a transistor in a manner that protects the first diode from direct exposure to negative voltages that would ordinarily cause the diode to break down in the absence of the transistor.

23. The wireless network of claim **22**, wherein the at least one repeater/amplification stage includes an MBMC matching network and one of an adaptively reconfigurable rectifier and a breakdown-protected rectifier.

(57) **ABSTRACT**

A system is presented for harvesting electromagnetic energy propagating in surroundings. The system comprises an antenna unit, a harvesting unit, and an input signal adapting circuit. The antenna unit is configured for receiving external electromagnetic radiation from the surroundings and producing a corresponding electric output. The harvesting unit comprises at least one energy harvesting circuit each configured and operable for receiving signals indicative of the output of the antenna unit and generating and storing corresponding electric charge, the harvesting circuit comprising: a rectifying unit comprising a plurality of rectifiers each configured and operable to receive AC electric signals and generate corresponding DC electric power; and a charge collection unit configured and operable to receive the plurality of DC electric powers from said rectifying unit and converting and accumulating them into the electric charge presenting harvested energy. The input signal adapting circuit has an input connected to the antenna unit and an output connected to the rectifying unit, the input signal adapting circuit being configured and operable for adjusting a predetermined electrical property of the antenna unit and rectifying unit to thereby optimize receipt of the electric output of the antenna unit to the harvesting circuit.

ENERGY HARVESTING SYSTEM

TECHNOLOGICAL FIELD AND BACKGROUND

[0001] The present invention is in the field of energy harvesting techniques and relates to an energy harvesting system which may be useful in various applications including medical devices (e.g. implantable devices), as well as electric vehicles, and various domestic devices.

[0002] In the last two decades, the usage of electromagnetic communication, such as RF communication, has dramatically increased in all aspects of human life, including mobile/satellite communication, medical treatments, and the like, while different parts of the radio frequency spectrum can be used for different radio transmission technologies and applications (e.g., as TV (television) or cellular applications). Generally, the radio frequency spectrum is shared by civil, government, and military users of all nations, according to International Telecommunications Union (ITU) radio regulations. Thus, people all over the world are surrounded by a variety of electromagnetic signals (radiation), which propagate in the air and have different frequencies and strength.

[0003] There have been several attempts in the art to collect electromagnetic signals which propagate in the air, and to generate electrical power. Some techniques of the kind specified are described for example in the following patents: EP 1,722,284, US 2009/105,782, and JP 10146077.

[0004] In recent years, there has been a rapid technological advance in medical implanted and attached devices. However, the majority of these devices, if not all, require electricity as their energy source. Each such medical device uses batteries as a disposable electricity source. When it comes to implanted devices such as a heart pace maker or a defibrillator, a change of a battery per se requires repetitive surgeries that endanger the patient and expose him to various risks along with the fears before a surgery, inconvenient of the procedure, and recovery period that comes after. When it comes to attached devices such as a hearing aid, the change of batteries that may vary from once a day to once a week according to the device type is merely a nuisance.

[0005] Thus, it is obvious that a mechanism, capable of charging a battery and possibly eliminating a need for battery in such devices, is desired.

GENERAL DESCRIPTION

[0006] There is a need in the art in a novel approach for energy harvesting enabling efficient collection and use of electromagnetic radiation (e.g., RF signals) and storage of the harvested energy in order to be supplied to an electrical load, such as a rechargeable battery or an electric device to enable for example, charging said battery or operating said electric device, in a most efficient manner. A technique for harvesting electromagnetic energy is described in U.S. patent application Ser. No. 13/116,554 of the same inventor incorporated herein in its entirety by reference. Such system functionally allows gathering the already existing RF radiation from the surrounding and converting it into usable energy source.

[0007] The present invention provides a novel energy harvesting system and method, as well as a novel antenna unit for use in an energy harvesting system. The antenna unit of the invention is configured for receiving external electromagnetic radiation from the surroundings and producing a corresponding output electric signal. The antenna unit comprises at least two electrically conductive elements associated with (e.g. positioned in) different transmission media having different electric and/or magnetic properties.

[0008] When harvesting RF energy from sources available in the air, the efficiency of the system is of critical importance due to the variety of frequencies and intensities of received signals. One of important factors determining the efficiency of a harvesting system is a degree of match/adjustment of a predetermined electrical property of the antenna unit and that of the rectifying unit. More specifically, this may be a match between the impedance of a rectifying circuit and the intensity of an input signal. The rectifier impedance is dynamically changing as a function of the intensity of the input signal. More specifically, when the input signal is a low power signal relative to the conductive threshold of the rectifier, the impedance of the rectifier is very high. As the intensity of the input signal increases and approaches the conductive threshold of the rectifier, the impedance of the rectifier decreases, until the intensity of the signal exceeds the conductive threshold of the rectifier and the impedance of the rectifier decreases. In a static system, the rectifier is configured such that it impedance matches a certain level of intensity of an input signal, but in other intensities it is not matched and the efficiency decreases significantly. Thus, there might be a need for an input signal adapting unit/circuit, e.g. an adaptive impedance matching unit, that is configured and operable for dynamically/selectively matching the rectifier impedance according to the changing input signal intensity to the impedance of the antenna unit.

[0009] One way of fulfilling a requirement for a dynamic change of impedance of the rectifier is by providing a dynamic active change of the input impedance. This technique however suffers from energy consumption leading to energy waste.

[0010] It is thus desired in some applications that such a dynamic impedance matching would be implemented by a passive unit. In this connection, it should be understood that the terms “passive unit” and “active unit” used herein refer to units/circuits which are, respectively, autonomously operable based on their predefined working parameters/conditions and operable by a dedicated controller to vary one or more of the working parameters/conditions. The invention provides such a passive filtering unit that operates to match the impedances of the rectifiers of different input intensity signals (received from the antenna unit) and maximize the efficiency of the harvesting system in all input intensity levels.

[0011] When harvesting electromagnetic energy, a capacitor of each rectifier is usually small. However, there is a need for storage of large quantities of charge originated from several rectifiers and from the same rectifier over time. The present invention provides a novel charge collection unit which may be based on either one of the two following novel approaches for gathering the small charges obtained during the harvesting process into a large storage (i.e. capacitor with relatively large capacitance). This is implemented in the invention either by using a switching topology circuit or by using appropriate conversion of voltage to current allowing transferring the small charges obtained to a large capacitor to enable large electric charge storage. To this end, the invention provides a charge collection unit comprising a signal summing unit which is configured and operable to receive a plurality of DC electric powers from multiple rectifiers of a rectifying unit and convert and accumulate them into the electric charge (via a voltage to current conversion or a switching topology circuit), where this charges presents the harvested energy.

[0012] Thus, according to one broad aspect of the present invention, there is provided a system for harvesting electromagnetic energy propagating in the surroundings to which the system is exposed. The system comprises: an antenna unit configured for receiving external electromagnetic radiation from the surroundings and producing a corresponding electric output; a harvesting unit comprising one or more harvesting circuits wherein each harvesting circuit is configured and operable for receiving signals indicative of the output of the antenna unit and generating and storing corresponding electric charge presenting the harvested energy; and an input signal adapting circuit which has an input connected to the antenna unit and an output connected to said at least one harvesting circuit of the harvesting unit and is operable for adjusting a predetermined electrical property of the antenna unit and said at least one harvesting circuit to thereby optimize receipt of the electric output of the antenna unit by said at least one harvesting circuit.

[0013] It should be noted that in this disclosure terms "unit" and "circuit" are used interchangeably because each of them actually refers to one or more electric circuits defining certain functionality for affecting/processing an electric input.

[0014] The harvesting circuit comprises a rectifying unit comprising a plurality of rectifiers each configured and operable to receive AC electric signals and generate corresponding DC electric power; and a charge collection unit configured and operable to receive the plurality of DC electric powers from said rectifying unit and converting and accumulating them into the electric charge presenting harvested energy.

[0015] Generally, the antenna unit may be of any known suitable configuration. Preferably, however, a novel antenna structure of the invention can be used. Such novel antenna structure comprises at least two electrically conductive elements associated with different transmission media differing in at least one of electric and magnetic properties. It should be understood that such a structure is termed herein as "antenna unit" solely in the meaning that it is responsive to electromagnetic radiation to which the structure is exposed (typically RF radiation) and providing a corresponding electric output (response signal).

[0016] In some embodiments, such at least two different transmission media may for example include at least two different animate tissues (in which case the antenna unit may be implanted in a subject); or may include animate tissue and air (in which case the antenna unit is attached to a subject). It should, however, be understood that the antenna unit of the invention is not limited to these examples, as well as is not limited to any specific media.

[0017] The input signal adapting unit is configured and operable to optimize receipt of the antenna output to the rectifying unit of the harvesting circuit by matching between the electric parameter, e.g. impedance, of the antenna unit and the rectifying unit.

[0018] In some embodiments, the input signal adapting unit comprises an impedance matching unit and a filtering unit connected to the impedance matching unit. The impedance matching unit is configured to match between the impedances of the antenna unit and the filtering unit. The filtering unit is configured and operable for sorting the received RF band propagating in the surroundings into a predefined number of subbands with predetermined values of central frequency, band width and strength for each subband. The predefined number of subbands corresponds to a number of the rectifiers in the rectifying unit.

[0019] In some embodiments, the input signal adjusting unit comprises an adaptive impedance matching unit, and a control unit connectable to the adaptive impedance matching unit and configured and operable operation thereof. The adaptive impedance matching unit is configured and operable to controllably adjust impedance of the rectifiers of the rectifying unit to signal intensities of multiple frequency bands received by the antenna unit.

[0020] In some embodiments, the charge collection unit comprises a signal summing unit comprising a switching topology circuit and a controller. The switching topology circuit comprises a predetermined number of capacitors corresponding to a number of the rectifiers in the rectifying unit, all electrically connected to a storage capacitor. The capacitors connected to output of the respective rectifiers have relatively small capacitance values, while the storage capacitor has a relatively large capacitance value. The switching topology circuit is adapted to controllably switch between the plurality of DC signals received from the plurality of rectifiers respectively with the corresponding plurality of the "small" capacitors for power summation and storage of corresponding charge on the "large" capacitor.

[0021] In some embodiments, the charge collection unit comprises a signal summing unit comprising a voltage to current unit. The voltage to current unit comprises a predetermined number of voltage to current conversion circuits having inputs connected to the outputs of the corresponding number of the rectifiers respectively, and having outputs connected to a storage a capacitor. The voltage to current unit is thereby adapted to convert and sum the plurality of DC signals/powers received from the plurality of rectifiers via the plurality of voltage to current conversion circuits.

[0022] The system may further comprise a control unit connected to at least one of the input signal adapting unit (e.g. impedance matching unit) and the charge collection unit. Considering the control unit is connected to at least the charge collection unit comprising a switching topology circuit described above, the control unit operates the switching topology to controllably switch between the plurality of DC signals received from the plurality of rectifiers respectively with the corresponding plurality of "small" capacitors of the relatively small capacitance values for power summation and storage of corresponding charge on the "large" capacitor.

[0023] It should be noted that the same input signal adapting unit may be associated with multiple harvesting circuits. Also, the same charge collection unit may be associated with multiple harvesting circuits by adjusting the number of inputs of the charge collection unit to the total number of rectifiers defined by the multiple harvesting circuits.

[0024] The harvesting unit may comprise a connection port for connecting output of the charge collection unit (defined by charge storage utility in the form of a large capacitor) to at least one electrical load. The at least one electrical load may include at least one of the following: a rechargeable battery, a medical device, an electric vehicle component, an electric device for home use. The medical device may include at least one of the following: a pacemaker, a defibrillator, and a hearing aid. The electric vehicle component may include at least one of the following: electrical accessories, audio systems and amplifiers, TV and DVD systems, GPS systems, air conditioning systems, alarm systems, lights and wiring systems.

[0025] In accordance with another broad aspect of the invention there is provided an antenna unit configured and operable for receiving external electromagnetic radiation from surrounding and producing a corresponding output electric signal. The antenna unit comprises at least two conductive elements positioned in at least two different transmission media being different in electric and/or magnetic properties. The received external electromagnetic radiation creates a potential difference between the at least two conductive elements producing an output electric signal, thereby allowing uptake of the external electromagnetic radiation from the surroundings.

[0026] As mentioned above, in some specific but not limiting examples, the different transmission media may include different animate tissues; or animate tissue and air.

[0027] In accordance with yet another broad aspect of the present invention, there is provided an input signal adapting unit for use with an antenna exposed to electromagnetic radiation of RF band propagating in surroundings. The input signal adapting unit comprises an impedance matching unit and a filtering unit connected to the impedance matching unit. The impedance matching unit is configured and operable to match between impedances of the antenna unit and the filtering unit, and the filtering unit is adapted for sorting the RF band into a predefined number of subbands of a predetermined frequency, bandwidth and strength for each subband.

[0028] The present invention in its further broad aspect is directed to a charge collection unit comprising a signal summing unit adapted to receive a plurality of DC electric signals and sum them in the form of an electric charge on a storage capacitor, the signal summing unit comprising at least one of a switching topology unit and a voltage to current unit.

[0029] The switching topology unit may comprise a predetermined number of capacitors having relatively small capacitance values and being connectable to output of a corresponding number of rectifiers respectively, and connected to said storage capacitor of a relatively large capacitance value. The switching topology unit is adapted to controllably switch between DC sources received from the rectifiers with the predetermined number of the capacitors for power summation.

[0030] The voltage to current unit may comprise a predetermined number of voltage to current conversion circuits having inputs connectable to outputs of a corresponding number of rectifiers respectively, and outputs connected to the storage capacitor. The voltage to current unit is thereby configured and operable to convert and sum a plurality of DC sources received from the plurality of rectifiers via the voltage to current conversion circuits.

BRIEF DESCRIPTION OF THE DRAWINGS

[0031] Examples illustrative of variations of the disclosure are described below with reference to figures attached hereto. In the figures, identical structures, elements or parts that appear in more than one figure are generally labeled with the same numeral in all the figures in which they appear. Dimensions of components and features shown in the figures are generally chosen for convenience and clarity of presentation and are not necessarily shown to scale. The figures presented are in the form of schematic illustrations and, as such, certain elements may be drawn greatly simplified or not-to-scale, for illustrative clarity. The figures are not intended to be production drawings.

[0032] The figures (Figs.) are listed below.

[0033] FIG. **1**A-**1**D are block diagrams schematically illustrating several examples of the configuration of an energy harvesting system of the present invention; wherein in the example of FIG. **1**A the operation mode of major components of the system is a passive mode that do not require additional adaptations for obtaining proper operation of the harvesting system; in the example of FIG. **1**B the operation mode of major components of the system is an active mode that requires adjustment of the operation of specific units of the system to a current condition of the harvesting process; and FIGS. **1**C and **1**D illustrate two examples of the system utilizing semi-active mode of the operation mode of major components of the system.

[0034] FIG. **2** is a schematic illustration of an example of an antenna unit of the present invention, being used with a heart pacemaker device implanted into a human body.

[0035] FIG. **3** is a schematic illustration of another example of the antenna unit of the invention being used with a hearing aid inserted into an individual's ear.

[0036] FIGS. **4**A-**4**B are block diagrams schematically illustrating an example of a two-elements antenna system of the invention configured and operable for receiving energy from the surrounding (FIG. **4**A), or connected to a transmitting unit (FIG. **4**B).

[0037] FIG. **5** is a schematic block diagram illustration of a filtering unit configured for maximizing the efficiency in an RF harvesting system.

[0038] FIG. **6** is a schematic block diagram illustration of a standard circuit for charging capacitors from rectifying elements.

[0039] FIG. **7** is a schematic block diagram illustration of a system for accumulating charge from small capacitors to a large capacitor.

[0040] FIG. **8** is a schematic block diagram illustration of a system for accumulating charge from small capacitors to a large capacitor in a charging switches position.

[0041] FIG. **9** is a schematic block diagram illustration of a system for accumulating charge from small capacitors to a large capacitor in a discharging switches position.

[0042] FIG. **10** is a schematic block diagram illustration of a system for accumulating charge from small capacitors to a large capacitor in a single discharging switch position.

[0043] FIG. **11** is a schematic block diagram illustration of a system for accumulating charge from small capacitors to a large capacitor by converting the stored electric charge to electric current source.

DETAILED DESCRIPTION OF THE EMBODIMENTS

[0044] Although various features of the disclosure may be described in the context of a single embodiment, the features may also be provided separately or in any suitable combination. Conversely, although the disclosure may be described herein in the context of separate embodiments for clarity, the disclosure may also be implemented in a single embodiment. Furthermore, it should be understood that the disclosure can be carried out or practiced in various ways, and that the disclosure can be implemented in embodiments other than the exemplary ones described herein below. The descriptions, examples and materials presented in the description, as well as in the claims, should not be construed as limiting, but rather as illustrative.

[0045] Reference is made to FIGS. **1A-1D** which show, by way of block diagrams, several embodiments of the configuration of an energy harvesting system of the present invention. The system includes such main constructional parts as an antenna unit **110**, and an energy harvesting unit **90** including one or more harvesting circuits each receiving and processing an output of the antenna unit **110**; and an input signal adapting unit **125**. The harvesting circuits includes a rectifying unit **140**, and a charge collection arrangement **150** which either includes a storage capacitor, or is connected to a separate storage unit **170** having such storage capacitor, for accumulating charge presenting harvested energy.

[0046] FIG. **1A** illustrates the energy harvesting system configuration **100**, in which the operation mode of major components is a passive mode, i.e. the mode that doesn't require additional adaptations for obtaining proper operation of the harvesting system. The system **100** includes the antenna unit **110**, the energy harvesting unit **90**, and the input signal adapting unit **125**. The harvesting unit **90** includes the rectifying unit **140**, and the charge collection arrangement **150**. In this example, the input signal adapting unit **125** includes an impedance matching unit **120** and a filtering unit **130** the operation of which will be described below. Also, in this example, the charge collection arrangement **150** includes a voltage to current converter **152**, as will be described more specifically further below.

[0047] Generally, the antenna unit may be of any known suitable kind. Preferably, the antenna unit **110** used in the system **100** utilizes the novel antenna configuration of the present invention. The antenna unit **110** of this novel configuration includes at least two electric conductors (conductive elements) **112** and **113**, which are positioned in at least two different substances constituting transmission media **115** and **116**, having different electrical and/or magnetic properties. Due to the different electrical and/or magnetic properties of substances **115** and **116**, RF radiation in the surrounding of the antenna unit creates different electric potentials on the conductive elements **112** and **113**. The potential difference between the two conductive elements is received by the harvesting unit **90** via the harvesting circuit and is then processed by the input adapting unit **125**. To this end, the signal undergoes impedance matching by unit **120** and filtering by unit **130** that operate together to adjust the impedance of antenna unit **110** to the impedance of the rectifying unit **140** to thereby allow optimal delivery of the received signal.

[0048] Generally, impedance matching unit **120** is used to enable transferring maximal electromagnetic energy/power from the antenna unit to the harvesting unit. In the configuration illustrated in this figure, the impedance of antenna unit **110** includes both the impedances of the transmitting media and the conductive elements that transfer the received energy into the harvesting unit. In order to transfer maximal electromagnetic power from the antenna into the harvesting unit, the impedance of the antenna, $Z_{Antenna}$, needs to be equal (generally as close as possible) to the complex conjugate of the harvesting unit impedance, $Z^*_{Harvesting\ unit}$, namely the following condition is to be satisfied:

$$Z_{Antenna}=Z^*_{Harvesting\ unit}$$

[0049] Impedance matching unit **120** may comprise appropriate electrical circuits which may contain a combination of capacitive elements and inductive elements. Generally, the impedance matching unit **120** may be of any suitable configuration known in the art.

[0050] The received signals are then delivered to the filtering unit **130**. Filtering unit **130** is configured and operable as a spectral filter and includes one or more arrays/sets of filters which sorts/divides the signals received from antenna unit **110** to predefined frequency bands. The spectral filtering process in accordance with the present invention is a non active process, in the meaning that is mainly directed to sort different signal frequencies that are characterized by having different strengths. A specific but not limiting example of a filtering unit is described in details further below with reference to FIG. **5**. The output of each of the last filters in the sets/arrays of filters is connectable to a dedicated rectifier in the plurality of rectifiers comprised in the rectifying unit **140**. The rectifier is configured to convert the respective filtered RF signal into a DC signal according to pre-expected signal strength, thus, eliminating the need for active matching process that usually consumes energy.

[0051] The rectifying unit **140** includes an array of rectifiers associated with a signal summing utility of the charge collection unit. The output of each rectifier is connected to such a signal summing utility that is adapted to receive plurality of DC electric signals, and perform their summation so as to allow storage thereof in a storage capacitor/unit **170**.

[0052] In this specific but not limiting example of FIG. **1A**, the output of each rectifier in the rectifying unit **140** is connected to the respective voltage to current conversion circuit in the voltage to current unit **152**. Voltage to current convertor unit **152** is configured and operable for summing several DC sources into one storage unit **170**. It should be noted that the voltage to current unit **152** is preferably configured to allow for passively accumulating several DC sources into the common storage without the need for active operations and without causing shortcuts and/or other interfering influences between the summed DC sources as normally occurs while connecting directly several DC voltage sources, as will be described in details hereinafter with reference to FIG. **11**. The storage unit **170** is configured to collect the entire harvested energy, and it may be further connected to one or more electrical loads (not shown) such as a rechargeable battery or an electric device.

[0053] FIG. **1B** illustrates another example of the energy harvesting system configuration **102** in which the operation mode of major components is an active mode that requires a control unit for adjusting the operation of specific units of the system to a current condition of the harvesting process. The system **102** is configured generally similar to the above described system **100** in that it comprises an antenna unit **110** which is preferably configured according to the invention, namely includes two conductors **112** and **113** positioned in different transmission media **115** and **116**, and comprises a harvesting unit **92** and an input signal adapting unit **125**. The harvesting unit **92**, similar to the above-described example includes, a rectifying unit **140**, and a charge collection arrangement **150**. In this example, the input signal adapting unit **125** includes an adaptive impedance matching unit **122** and a control utility **180**. The adaptive impedance matching unit **122** is configured to adjust the impedance of antenna unit **110** to the impedance of the rectifying unit **140** to thereby allow optimal delivery of the received signal.

[0054] Generally, in order to harvest energy from electromagnetic waves there is a need to rectify the harvested energy that is received from the antenna unit to thereby receive a DC electrical energy that can be reused as an energy source. The input characteristic impedance of the rectifying unit is not stable and can be varied from some Ohms to Mega Ohms as a function of the input RF level on the rectifier input. In addition, the antenna unit characteristic impedance can be stable or unstable. One technique that allows for adapting stable or unstable antenna to an unstable input impedance front end circuit is an adaptive impedance matching technique.

[0055] Adaptive impedance matching unit **122** is configured and operable by the control unit **180** to constantly adapt the antenna impedance into an unstable characteristic impedance of the harvesting circuit. To this end, the control unit **180** operates to control the parameters of the impedance matching unit to match the impedance of the rectifier to that of the antenna unit. The control unit **180** is operable to vary the impedance of the impedance matching unit **122** in accordance with the input voltage on the harvesting circuit. The control unit **180** is configured and operable to maximize the efficiency of the electrical system by varying the impedance of the impedance matching unit **122** in accordance with electrical characteristics measured in predetermined locations along the circuit. The control unit **180** operates to vary at least one of input and output impedance values of the impedance matching unit to maximize the voltage in predetermined locations. The control unit may be an electronic unit preferably configured of linear electronic elements or a software utility operating on an electronic device. The control unit has at least two input ports for detecting electrical parameters at said predetermined locations, a comparator module for comparing the detected parameters, and at least one output port for providing a control signal to the impedance matching unit to thereby vary its impedance. In the specific example illustrated in FIG. 1B, the control unit **180** is adapted to control the adaptation of the impedance according to the strength of the signal received.

[0056] The received signal is then delivered to a rectifier in the rectifying unit **140** that is adjusted to convert the RF signal into a DC signal. The output of each rectifier of the rectifying unit **140** is connected to the charge collection arrangement **150**. In the example of FIG. 1B, the charge collection arrangement **150** includes a switching topology unit **190** and a control utility and is configured and operable to allow summing several DC sources into one storage capacitor unit **170**. The control utility of the charge collection arrangement **150** and that of the input signal adapting unit **125** may be incorporated in separated controllers or may be parts of the same control unit **180**. The switching topology unit **190** includes several switching circuits, the operation of which is controlled by the respective control utility (e.g. in the control unit **180**). A detailed description of an example of the switching topology unit is described below with reference to FIG. **6-10**. The storage unit **170** collects the entire harvested energy, and as mentioned above may further be connected to a rechargeable battery or to an electrical device.

[0057] FIG. 1C exemplifies a harvesting system **103** in which the operation mode of major components is a semi-active mode that requires a control unit for adjusting the operation of the system to the current stage of the harvesting process. The system **103** is configured generally similar to the above described systems **100** and **102** comprising an antenna unit **110** preferably including two conductors **112** and **113** positioned in different transmission media **115** and **116**, a harvesting unit **93** and an input signal adapting unit **125**. The harvesting unit **93** has at least one harvesting circuit for receiving the RF output of the antenna unit. The harvesting unit **93** each harvesting circuit thereof, similar to the above-described examples, includes a rectifying unit **140**, and a charge collection arrangement **150** including or connected to an energy storage capacitor unit **170**. The system **103** is similar to the above-described unit **102** (FIG. 1B) in that input signal adapting unit **125** includes an adaptive impedance matching unit **122** and a control utility constituted by a control unit **180**. The adaptive impedance matching unit **122** is configured and controlled by the control unit **180** to adjust the impedance of the antenna unit **110** to the impedance of the harvesting unit **93** (rectifying unit) to thereby allow optimal delivery of the received signal, e.g. by controlling the adaptation of the impedance according to the strength of the signal received. The harvesting unit **93** is similar to the above-described unit **90** (FIG. 1A) in that its charge collection arrangement **150** is configured as a voltage to current convertor. Thus, the received antenna signal is delivered to a rectifier in the rectifying unit **140** that is adjusted to convert the RF signal into a DC signal. The output of each rectifier is connected to the voltage to current unit **152** which allows summing several DC sources into one storage unit **170** configured to collect the entire harvested energy. As indicated above, the storage unit may further be connected to a rechargeable battery or to an electrical device (not shown).

[0058] FIG. 1D illustrates yet another example of an energy harvesting system **104** utilizing a semi-active mode of operation of the major components of the system. The system **103** is configured generally similar to the above described systems **100**, **102** and **103** comprising an antenna unit **110** preferably including two conductors **112** and **113** positioned in different transmission media **115** and **116**, a harvesting unit **94** having at least one harvesting circuit for receiving the RF output of the antenna unit, and an input signal adapting unit **125**. The harvesting unit **94** (each harvesting circuit thereof), similar to the above-described examples, includes a rectifying unit **140**, and a charge collection arrangement **150** including or connected to an energy storage capacitor unit **170**. The system **104** is similar to the above-described unit **100** (FIG. 1A) in that its input signal adapting unit **125** includes an impedance matching unit **120** and a filtering unit **130** that are configured to adjust the impedance of antenna unit **110** to the impedance of rectifying unit **140** to thereby allow optimal delivery of the received signal. The harvesting unit **94** is similar to the above-described unit **92** (FIG. 1B) in that its charge collection arrangement **150** includes a switching topology unit **190** and a control utility constituted by a control unit **180** and is configured and operable to allow summing several DC sources into one storage unit **170**.

[0059] The received signal is delivered to a rectifier comprised in rectifying unit **140** that is adjusted to convert the RF signal into a DC signal. In accordance with the variation illustrated in this figure, the output of each rectifier of rectifying unit **140** is functionally connected to the switching topology circuit in switching topology unit **190** that allows summing several DC sources into one storage capacitor unit **170**. The switches position for charging/discharging configuration is determined by control unit **180**.

[0060] It should be noted that the principles of the present invention are not limited to any specific configuration of any one of the above mentioned units and any known suitable configuration can be used in the system of the invention as any men skilled in the art may configure, provided these units have the above described functional features for implementing the technique of the invention. In addition, the harvesting system provided herein may comprise off the shelf antenna, while preferably at least two antenna elements are positioned in different substance (transmission media). As described above, such antenna unit of the present invention provides maximal gain enhancement due to different transmission media surrounding the conductive elements that functionally create an antenna effect that allows uptake of electromagnetic radiation from the surroundings.

[0061] The conductive elements are inserted or attached to at least two different transmission media with different electrical and/or magnetic properties (e.g. permeability, permittivity, and conductivity) in order to increase the antenna maximal gain to functionally allow better performance of the antenna. In some applications of the invention, at least one conductive element of such novel antenna unit is positioned in contact with a user's body. The different transmission media can thus be, but not limited to, skin and air if the antenna is attached to a body or it can be, but not limited to, two different tissue types such as muscle and fat, muscle and intracellular fluid, muscle and fat tissue, dermis and fat tissue, and any other combination thereof, when the antenna is implanted in a body. The novel antenna may also be applicable for uses outside animate bodies, as long as the conductive elements are positioned in at least two different substances that differ from each other in their electrical and/or magnetic properties.

[0062] The general theory of electromagnetic phenomena is based on Maxwell's equations, which constitute a set of four coupled first-order partial-differential equations resulting the space and time changes of electric and magnetic fields to their scalar source densities (divergence) and vector source densities (curl). For stationary media, Maxwell's equations in the differential form are:

$$\nabla\cdot D(r,t)=\rho(r,t)\text{(Gauss's electric law)} \tag{1}$$

$$\nabla\cdot B(r,t)=0\text{(Gauss's magnetic law)} \tag{2}$$

$$\nabla\times E(r,t)=-\partial B(r,t)/\partial t\text{(Faraday's law)} \tag{3}$$

$$\nabla\times H(r,t)=\partial D(r,t)/\partial t+J(r,t)\text{(Ampere's law)} \tag{4}$$

wherein E is the electric field intensity [volt/meter]; H is the magnetic field intensity [Ampere/meter]; D is the electric flux density [Coulomb/square meter]; B is the magnetic flux density [Tesla or Weber/square meter]; ρ is the free electric charge density [Coulomb/cubic meter]; and J is the free electric current density [Ampere/square meter].

[0063] Maxwell's equations involve only macroscopic electromagnetic fields and, explicitly, only macroscopic densities of free charge p(r,t) giving rise to the free current density J(r,t). The effect of the macroscopic charges and current densities bounded to the medium's molecules is indicated by auxiliary magnitudes D and H, which are related to the electric and magnetic fields E and H by the so-called constitutive equations that describe the behavior of the medium. In general, the quantities in these equations are functions of the position (r) and the time (t).

[0064] The power density that the electromagnetic field carries in the free space is defined by Poynting's vector:

$$S=E\times H\text{[Watt/square meter]} \tag{5}$$

which represents the power passing through a unit area perpendicular to the propagation vector r. Inside matter, the power density S_v [Watt/cubic meter] is related to the work (or heat) supplied to the charge distribution:

$$Sv=dS/dv=E\cdot J \tag{6}$$

known as the point form of Joule's law.

[0065] Inside matter, additional physical quantities are introduced to describe the interaction of waves with molecules. The electric permittivity ∈ is connected to the electric field and to the electric flux, but also to a new macroscopic vector P [Coulomb/square meter] called the electric polarization vector, such as:

$$D=\in E+P \tag{7}$$

[0066] For most materials, being linear isotropic media, especially the human body tissues, the macroscopic vector P can be considered as co-linear and perpendicular to the applied electric field. Thus, we get:

$$P=\in\chi_e E \tag{8}$$

wherein χ_e is the electric susceptibility of the matter (i.e. capability of the matter to be polarized) and D can be written as:

$$D=\in_o\in_r E \tag{9}$$

[0067] The magnetic behavior in matter involves a similar treatment with the following relations:

$$H=B/\mu-M \tag{10}$$

$$M=\chi_m H \tag{11}$$

$$B=\mu_o\mu_r H \tag{12}$$

wherein μ is the magnetic permeability and χ_m is the magnetic susceptibility. Since the human body has very minor magnetic effects we neglect here the magnetic nature of the tissues and consider only their electric nature. Very often the relation between the electric field E and the current density J is given at any specific point by Ohm's law:

$$J(r,t)=\sigma E(r,t) \tag{13}$$

wherein σ [mho/meter] is the conductivity of the matter.

[0068] Now the configuration of electromagnetic waves is considered in the boundaries between air ("transmission medium A") and matter ("transmission medium B"). In free space, the existing fields are pure electric field E and magnetic field H and the power density obeys Poynting's law with $\in_r=1$ and $\mu_r=1$. In the human body, the fields are presented by the electric flux density D and magnetic field intensity H (because in case of no magnetic effects B=H), and the local parameters are electric permittivity c (actually a complex number written as $(\in_o(\in'+j\in''))$ and conductivity of the matter σ.

[0069] When a plane wave propagating in free space interacts with the human body, part of the energy of the wave is reflected back to air and part of the energy penetrates into the body. From the penetrating part, some portion continues to propagate inside the body and some portion is absorbed by the tissues and bones. The absorbed power can be summed as the integral of many local interactions:

$$S\text{(absorbed)}=0.5\int Pv\,dv=0.5\int(E\cdot J)dv=0.5\int\sigma|E|^2dv \tag{14}$$

[0070] The factor of 0.5 is indicative of that the dissipation is related to average power and not to the peak power. The absorbed power in the human body is often expressed by the term SAR (Specific Absorption Rate) which is no other than:

$$\text{SAR}=(\sigma/2\rho)|E|^2 \tag{15}$$

wherein σ is the conductivity [mho/meter] in any specified area and p is the mass density [kg/cubic meter] in any specified area. The units of the SAR quantity are therefore [Watt/kg]. SAR is the most commonly used indicator and measure for safety standards in RF exposure.

[0071] The next table exemplifies the tissues dielectric constant and conductivity for several tissues at 900 MHz:

Tissue	ϵ_r	σ (S/m)
Skin	35	0.6
Muscle	58	1.4
Fat	6	0.08
Spinal cord	49	1.1
Blood	62	1.5
Cartilage	35	0.6

[0072] The novel antenna unit described above preferably utilizes miniature antenna elements. For example, the maximal size of the conducting element of the antenna is significantly smaller than the wavelength for which the antenna is designed. Thus, it reduces substantially the form factor of the antenna and therefore, reduces the burden of carrying it. Moreover, the miniature size of the conductive elements allows it to be transplanted in an animate body in general and in a human body in particular.

[0073] The conductive elements may be of any suitable shape, such as but not limited to a ring shape (e.g. conductive pad) or of a line shapes (e.g. conductive wire).

[0074] In some applications of the invention, the antenna unit is used with a medical device. The antenna receives external electromagnetic radiation from the surroundings and produces a corresponding output electric signal for operating the medical device.

[0075] It should be noted that although in the above described examples the novel antenna unit of the present invention is shown as being used in electromagnetic harvesting systems to provide an improved intake of energy from the surroundings, this antenna unit may be utilized in communication systems for transmitting and receiving data, as well as medical applications for communication, for example, for data/signal exchange between an implanted medical device and an external element/system.

[0076] In a specific but not limiting example of the invention, the novel antenna unit may be implanted in and/or attached to a human body being used along with a medical device such as a pacemaker, a cardiac defibrillator, a hearing aid, an orthopedic electrical pulse producing device, and any other electric device that may be implanted in or attached to an animate body.

[0077] In this connection, reference is made to FIG. **2** that schematically illustrates the use of the system of the invention with an implanted medical device, where the antenna unit **210** is connected to an internal organ in the human body **200**. In this example, the antenna unit **210** is implanted in a heart **201** of a human body **200** and a harvesting unit **90** is associated with (integral in or connected to) a defibrillator **270**. Conductive elements **212** and **213** of the antenna unit **210** are imbedded in two different transmission media **215** and **216** respectively, which may, for example, be a fat layer surrounding the heart and a heart muscle. Due to the difference in the electrical properties of these two media **215** and **216**, they differently interact with RF radiation in the surrounding and consequently different electric potentials are obtained in the substances and accordingly on the conductors **212** and **213** thereby creating an antenna effect and transmitting the electromagnetic radiation from the surrounding to the harvesting unit **290**. Although in the illustration in the figure an input signal adapting unit is shown as a separate unit connected to the harvesting unit **290**, it should be understood that such an input signal adapting circuit may be integral with the harvesting unit as shown in the non limiting examples of FIGS. **1**A-**1**D. Also, it should be noted that although in this example, the input signal adapting unit is referred to as an impedance matching unit **220**, the input signal adapting unit, as well as the entire harvesting unit (receiver) **290** may be configured and operable according to any of the above-described examples of FIGS. **1**A-**1**D. Alternatively, as mentioned above, the system may utilize the novel antenna unit of the invention connected to any known suitable energy harvesting device having any known suitable impedance matching circuit. Thus, the antenna unit **210** is connected via the harvesting unit **290** to the defibrillator **270**. It should be clear that all circuits and devices described in this figure are drawn schematically to emphasize the overall configuration.

[0078] Reference is made to FIG. **3** that schematically illustrates how the present invention can be used in another medical application. Here, the system of the invention is associated with a hearing aid **380**. As shown in the figure, an antenna unit **310** is attached to an ear **300** such that a conductive element **312** of the antenna unit is held in air (constituting a transmission medium **315**), while a conductive element **313** is by its one end attached to ear **300** (constituting a different transmission medium **316**). The conductive elements **312** and **313** by their free ends are connected to a harvesting unit **390**; in the present not limiting example, the connection is via a separate input signal adapting unit, which has an impedance matching circuit **320**. The output of harvesting unit **390** (e.g. its storage unit) that is connected to the hearing aid **380**. All circuits and devices are drawn schematically to emphasize the overall configuration. As mentioned above, it should be understood that the harvesting unit together with impedance matching circuit may have any known suitable configuration, but preferably is configured as exemplified above with reference to FIGS. **1**A-**1**D.

[0079] Reference is now made to FIGS. **4**A and **4**B that illustrate two examples of antenna systems of the present invention denoted **400** and **400'** respectively. The systems are configured as a two-element receiving antenna, in which the antenna unit **410** includes conductive elements **412** and **413** embedded in different transmission media **415** and **416** respectively. In these specific non-limiting examples, the conductive element **412** has a closed-loop configuration or is a ring-like element (e.g. termed "conductive pad"), while conductive element **413** is a substantially straight strip-like element (e.g. termed "conductive wire"). It should be understood that the conductive elements may have any shape/geometry, e.g. both may be in the form of conductive pads or conductive wires.

[0080] In the example of FIG. **4**A, conductive elements **412** and **413** are connected via an impedance matching unit/circuit **420** to a harvesting unit **490** (e.g. configured according to the invention as described above, or any other energy collection unit) the output of which may be further connected to an electrical load (not shown). In the example of FIG. **4**B, the conductive elements **412** and **413** are connected through an impedance matching unit/circuit **420** to a transmitting unit **460** configured for transmission of data.

[0081] The impedance matching unit **420** may include an adaptive impedance matching circuit as exemplified with reference to FIGS. **1**B and **1**C, or alternatively may include an impedance matching circuit connected to a filtering unit as exemplified in general above with reference to FIGS. **1**A and **1**D and will now be described more specifically with reference to FIG. **5**.

[0082] The present invention, in its another aspect, provides a novel input signal adapting unit configured for maximizing the efficiency of the energy collection system. To this end, the input signal adapting unit is configured as a dedicated passive impedance matching filtering circuit formed by an impedance matching unit/module and a filtering unit/module. The configuration and operation of the filtering unit is based on the fact that in an RF harvesting system from the environment, the frequency and intensity (strength) of most harvested signals can be predefined, i.e. are either known a priori or are predictable, and therefore by using frequency filtering one can actually differentiate/sort the received signal for different intensities (strengths).

[0083] For example, there are typically two major categories of signals expected in be input signals for an RF harvesting system from the environment, both originated from the mobile phone RF system. The first is the signal from the base station to the cellular phone (downlink) and the second is the signal from the cellular phone to the base station (uplink) The downlink signal is characterized by a relatively low level signal and a different frequency than the uplink signal having a higher intensity. RF radio signals are also expected to be with the same frequency and intensity characteristics of as the downlink signals.

[0084] The filtering unit may include a preliminary wide band pass filter circuit with a wide enough frequency band to include both uplink and downlink frequency bands, and two or more narrow band filter circuits (defining at least one pair of such narrow band filters), one or more of them configured for the uplink frequency band(s) and one or more other of them configured for the downlink frequency band(s). The first wide band filter is responsible for receiving RF signal from the harvesting antenna and allowing passage of signals of both uplink and downlink frequencies. Each narrow band filters is responsible for allowing passage of AC signals in the appropriate frequency band, and accordingly in the appropriate corresponding intensity, to a dedicated rectifier so as to match the impedance of the rectifier according to the expected input intensity. The narrow band filters may be operable in parallel so as to simultaneously allow passage of AC signals in different narrow frequency bands.

[0085] It is understood that in different geographic locations, the expected frequency range and expected intensity may be different, and therefore the selection of the wide band filter and the narrow band filters may vary from country to country and from region to region and/or the filter circuit may include more than one pair (e.g. a large number of pairs) of filters to cover multiple combinations of the wide band filter and the narrow band filters.

[0086] It is understood that change in mobile (cellular) technology and/or mobile (cellular) transmission protocols may define various frequency bands that will be available for harvesting from the environment. However, due to ability of predicting their frequency and intensity, a dedicated narrow band filter and a corresponding rectifier can be designed.

[0087] It should be understood that the cellular uplink and downlink RF signals discussed above are only examples of available RF signals in the air, and other signals are within the scope of the present invention. The above aspect of the invention is exemplified in FIG. **5** which is a schematic block diagram illustration of a filtering unit **500** of the invention for maximizing the efficacy in an RF harvesting system. The filtering unit **500** includes a wide band filter **510** having an input that may receive an alternating current radiofrequency signal from a harvesting system antenna (not shown), and an output which is connected to narrow band filters—two such filters **521** and **522** being shown in the example of FIG. **5**. Narrow band filter **521** is designed to allow passage of signals in the uplink frequency range of the cellular system and is connected in parallel to the narrow band filter **522**, which is designed to allow passage of signals in the downlink frequency range of the cellular system. Wide band filter **510** is configured for passing both of the uplink and the downlink frequency bands.

[0088] Narrow band filter **521** is connected to a dedicated rectifier **531** designed for receiving signals of an expected strength, and narrow band filter **522** is connected to another dedicated rectifier **532** that is similarly designed for optimally obtaining signals of the expected frequency and strength from filter **522**. The impedance of each of the rectifiers **531** and **532** is matched according to the expected intensity parameters (strength) in the specific frequency band, originated from the RF system.

[0089] For realization of the exemplary filtering unit described above, a numeric example is herein provided: A radiation band having a central frequency of 1 GHz and bandwidth (BW) of 800 MHz is received by the antenna. This band contains desired frequencies that need to be harvest. The frequencies in accordance with this specific example are 915 MHz and 950 MHz. The received band is transferred from the antenna to the first wide band filter that allows transmission of a 60 MHz band centered at 930 MHz. The received signals obtained from the first filter are thus between the frequencies of 900 MHz to 960 MHz. The parallel second and third narrow band filters are now receiving signals between 900 MHz to 960 MHz, while the second filter is set to center frequency 915 MHz with BW of 30 MHz and the third filter is set to center frequency of 945 MHz with BW of 30 MHz. The received signals' strength in the band of 915 MHz are predicted to be in the range of (−30) dbm to (−20) dbm, and the received signals strength in the band of 950 MHz are predicted to be in the range of (−5) dbm to 5 dbm.

[0090] The rectifier unit connected to the filtering unit includes a corresponding number of rectifiers, the rectifier connected to the second band pass filter is matched to rectify signal strength in the range between (−30) dbm to (−20) dbm and the rectifier connected to the third band pass filter is matched to rectify signal strength in the range between (−5) dbm to 5 dbm.

[0091] It should be understood that the invention is neither limited to a number of filters in the filtering unit described above, nor to any specific frequency bands. Additional signals propagating in the surroundings of the antenna and suitable to be used by such filtering circuit, include those having the priori known frequency and strength of a commercial radio channel. The expected signal strength received from a commercial radio channel is from (−50) dbm to −40 dbm. In this case, the filter may be set for the channel frequency and the corresponding rectifier may be matched to a strength range of (−50) to (−40) dbm. In case of parallel radio channels, for example, between 88 MHz and 108 MHz, the receiver (e.g.

harvesting unit) can be matched to the strength of the entire band received from the band pass filter.

[0092] The present invention in its yet further aspect provides a novel charge collecting unit suitable to be used in the energy harvesting system. The charge collecting unit of the present invention is configured as a signal summing utility adapted for accumulating charge from relatively small capacitor units to a large capacitor unit.

[0093] In some embodiments of the invention, such signal summing utility is configured to appropriately accumulate charge mainly by changing the topology of various components of the unit. In this case, the summing utility may include such functional modules/circuits as a relatively small storage charging circuit, and a switching circuit, connected to a relatively large storage charging circuit (which may be that of the storage unit in the harvesting system).

[0094] The small storage charging circuit includes a plurality of capacitor units. The small storage charging circuit may for example be adapted for accumulating charge obtained from the output of the rectifying unit (i.e. plurality of rectifiers) and for storing the charge created on multiple capacitor units. Each of the capacitor units in the small storage charging circuit may include a plurality of capacitors being in serial and/or parallel connections.

[0095] The switching circuit may be adapted for determining the mode of the circuit, defining the function thereof as a charging function or as a discharging function. The discharging of the small storage charging circuit may be performed simultaneous or single charging unit at a time, or according to predetermined time pattern for multiple storage charging units. The plurality of switches in the switching circuit may be operated independently, as well as may be connected and switched (operated) according to a predetermined switching pattern, for example a certain switch is activated depending on the operative state of the locally adjacent switches. The plurality of switches in the switching circuit may be controllably operated as exemplified above with reference to FIGS. **1**B and **1**D.

[0096] The charge collection unit of the present invention may be designed to be associated with a plurality of harvesting units. Each harvesting unit may capture RF energy, rectify and store the energy as a charge on a capacitor unit. In some embodiments of the present invention, the plurality of harvesting units may capture plurality of frequency bands, wherein each harvesting unit may be adapted to capture a specific frequency band. Additionally or alternatively, at least two harvesting units may be adapted to capture similar frequency band.

[0097] The large storage charging circuit may be adapted for accumulating and storing the charge pre-stored in each of the plurality of small capacitor units in a large storage charging unit for further usage. The large storage charging circuit may include a plurality of capacitors in serial and/or parallel connections. The output of the large storage charging circuit may for example be followed by one or more of the following: a step up convertor; a voltage stabilizer; a battery charging circuit; a capacitor array, an electrical load. In some embodiments, the output of the large storage charging subunit may be either switched or constantly short to the circuit.

[0098] Some examples of various switching options are provided below with reference to FIGS. **6-10**.

[0099] FIG. **6** is a schematic block diagram illustrating a standard charge collection circuit **600** that might be used in the energy harvesting system of the invention. The collection circuit **600** includes a plurality of charging capacitor units—three such units **621**, **622**, and **623** being shown in this non-limiting example. In this example, the charge collection circuit **600** operates for collecting charge from a rectifying unit including a plurality of rectifier elements—three such elements **611**, **612** and **613** being shown in this non-limiting example. Each charging capacitor unit is connected to a corresponding one of the rectifier elements and connected to ground. Each of the rectifiers **611**, **612** and **613** receives AC signal from a harvesting antenna unit or from any other element positioned between the antenna unit and the rectifier (e.g. input signal adapting unit, e.g. impedance adaptor), rectifies the signal, and the corresponding energy is stored as electric charge in the corresponding one of the capacitor unit **621**, **622**, and **623**. It is understood that each capacitor unit may be configured as a single capacitor unit or multi-capacitor unit where the multiple capacitors may be connected in any serial and/or parallel connections. It is understood also that each rectifier element may receive AC signal in a similar or different frequency band. It should be noted that the circuit **600** is neither limited to a specific number of rectifier-capacitor arrangements nor to a specific electrical connection of the capacitors, and FIG. **6** is just an example of the operational principles of the charge collection unit.

[0100] Reference is now made to FIG. **7** which is a schematic block diagram illustration of a charge collection unit **700** configured and operable according to the present invention. The charge collection unit **700** is operable as a signal summing unit, and includes a plurality of small capacitor units—thee such units **721**, **722** and **723** being shown in this non-limiting example. The capacitor units **721**, **722** and **723** are at one ends connected via switching circuits to rectifiers **711**, **712** and **713** respectively, and at the other ends are connected to ground **750**. Also provided in the charge collection unit **700** is a large capacitor unit **740** which is connected to the capacitor units **721**, **722** and **723** via the switching circuits. The switching circuits include a plurality of switches **731**, **732**, **733**, **734** and **735**, each configured with two working/operative positions **1** and **2**. The distribution of switches positions between positions **1** and **2** determine the functionality of the switching circuit, as will be described with reference to FIGS. **8** and **9**. As shown in the figure, the switches **731**, **733** and **735** selectively connects the charge collection unit **700** to the rectifying unit.

[0101] Thus, each rectifier receives AC signal from a harvesting antenna or from any other intermediate circuit communicating the antenna signal to the rectifier. The energy rectified by each of the multiple rectifiers of the rectifying unit is being stored as electric charge in the corresponding capacitor unit of the charge collection unit **700**. As shown in the figure in a self-explanatory manner, each capacitor unit is on its other end selectively connectable either to ground **750** or to the large capacitor unit **740** through the corresponding two-state switches, and on its other end is selectively connectable either to the respective rectifier or to the large capacitor unit **740** through the other two-state switches.

[0102] The charge collection unit operates in the following manner. The switches **731-735** are controlled by the controller, which can turn them to any given mode (charging/discharging) based on real time monitoring of each of the capacitors **721-723** connected to the outputs of the rectifiers. Based on the information (voltage level) received from each capacitor, the controller can determined as to whether to keep the circuit in the charging mode or whether it is ready to discharge into the storage capacitor. The received information from the capacitors **721**-**723** can also be indicative of whether the harvesting process is ongoing, and whether the reached voltage level is maximal at the time. Based on this information, the controller turns the switches into charging or discharging mode.

[0103] Further, the controller can define a full discharge mode (when all the capacitors are discharged together), semi discharge mode (only some of the capacitors are discharged while the others remain in charging mode), and charging mode (all capacitors are being charged).

[0104] Another option for the controller operation is based on a programmable pattern (i.e. predefined values). When the voltage of the capacitor **721**-**723** reaches a certain voltage level (as being defined), the switches are turned to the discharge mode. When the discharge is complete (can be defined as well), the switches are being turned back into the charging mode. This method allows three modes: full discharging, semi discharging and full charging.

[0105] It is understood that each of capacitor units **721**, **722**, and **723** may be configured as a single capacitor unit or as a multi-capacitor unit in which an array of capacitors are connected in some combination of serial and parallel connections. Similarly, that the large capacitor unit **740** may have a single-capacitor configuration or may be a multi-capacitor circuit utilizing a proper serial and/or parallel connection between the capacitors.

[0106] It should be understood that the configuration exemplified herein is neither limited to a number of rectifiers in the rectifying unit nor to a number of small capacity units in the charge collection unit **700**. It should also be clear that all circuits and devices described in this figure are drawn schematically to emphasize the overall configuration.

[0107] FIGS. **8** and **9** schematically illustrate another example of a charge collection or signal summing unit **800** of the invention. The charge collection unit **800** is configured generally similar to the above described unit **700**, namely includes multiple small capacitor units denoted as **821**, **822** and **823** connected to multiple rectifiers **811**, **812**, **813**, respectively, of a rectifying unit, and connectable to a large capacitor unit **840** in a charging configuration via switching circuit including multiple switches **831**, **832**, **833**, **934** and **835**. The capacitor units **821**, **822** and **823** are at one ends connected to the rectifiers, and at the other ends are connected to ground **850**.

[0108] As mentioned above, the small capacitor units **821**, **822**, and **823** as well as large capacitor unit **840** may include single-capacitor configuration(s) or multi-capacitor configuration(s) connected to one another in serial and/or parallel connections. Also, the invention is not limited to a number of rectifiers in the rectifying unit; the number of small capacity units is selected in accordance with the number of the rectifiers. Further, as also mentioned above, all circuits and devices described in this figure are drawn schematically to emphasize the overall configuration.

[0109] The configuration **800** is different from the above-described example of FIG. **7** in a somewhat different configuration of switching elements **831**, **832**, **833**, **834** and **835**. Each of the switches **831**, **833**, **835** selectively connects the respective capacitor unit to the corresponding rectifier or to the large capacitor unit **840**, and the other switches selectively connect the respective capacitor units to ground **850** or to the large capacitor unit **840**.

[0110] FIG. **8** shows the switching configuration of the summing unit **800** corresponding to a charging configuration. Each capacitor unit is connected directly to its corresponding rectifier and is being charged. It is understood that capacitor units **821**, **822** and **823** may be charged in different charges.

[0111] FIG. **9** shows the signal summing unit **800** of FIG. **8** in a discharging configuration. As shown, the switching elements **831**, **832**, **833**, **834** and **835** are in a switch position topology connecting each of small capacitor units **821**, **822** and **823** to the large capacitor unit **840**. In this discharging configuration all small capacitor units **821**, **822** and **823** are connected in series and their resultant capacitor is connected in parallel to the large capacitor unit **840**, i.e. electrical charge is being transferred from small capacitor units **821**, **822**, and **823** to large capacitor unit **840**. The change of the switching state from the topology described in FIG. **8** to the topology described in FIG. **9** results in charge transfer from small capacitor units **821**, **822** and **823** to large capacitor unit **840**. Since the voltage across the small capacitor units is higher than the voltage across the large capacitor unit **840**, the flow of charge is directed from small capacitor units to large capacitor unit until equilibrium is reached.

[0112] FIG. **10** exemplifies a signal summing unit **800** of FIGS. **8**-**9** modified to have a single discharging configuration. In the scenario illustrated in this figure, switching elements **831**, **832**, and **835** are in a switch position topology connecting small capacitor units **821**, and **823** to rectifiers **811** and **813** respectively on one side, and to ground **850** on the other side, while being disconnected from the large capacitor unit **840**. This switching configuration is a charging configuration of capacitors **821** and **823** from rectifiers **811** and **813** respectively associated with harvesting unit/units. However, switching elements **833** and **834** are positioned in a topology that allows for connecting small capacitor unit **822** to the large capacitor unit **840** in a parallel configuration, i.e., in a discharging position. In other words, in the scenario illustrated in FIG. **10**, one or more of the capacitor units may be discharged while one or more other capacitor units remain charged: small capacitor unit **822** may be discharged to large capacitor unit **840** while the other capacitor units **821** and **823** remain charged.

[0113] In accordance with the example of FIG. **10**, switching elements **833** and **835** are configured with three optional positions, each changing the topology of the circuit and its functionality. These switching elements, when being in the first operational state/position, connect the small capacitor units **822** and **823** to respective rectifiers **812** and **813** thus allowing charging of capacitor units **822** and **823**. When in the second operational position of switching elements **833** and **835** they create serial connection of the small capacitor units **821**, **822** and **823** to thereby allow simultaneous discharge of the small capacitor units to the large capacitor unit **840**. The third operational position of these switching elements allows direct discharge of the small capacitor unit **822** or **823** to the large capacitor unit **840**. It should be understood that the small capacitor unit **821** might be capable of being discharged autonomously, directly to the large capacitor unit **840**.

[0114] As indicated above, this embodiment of the summing unit is also not limited to any specific number of small capacitor units, and this number corresponds to a number of rectifiers in a rectifying unit, and that all circuits and devices described in this figure are drawn schematically to emphasize the overall configuration.

[0115] As described above with reference to FIGS. **1**A and **1**C, in some embodiments of the invention the charge collection unit or signal summing unit allows accumulation of charge in the harvesting system by converting the electric voltage developed on capacitors, connected to the outputs of rectifiers, into electric current source. In such variation, the summing unit includes a small storage charging utility/circuit, a voltage to current converter utility/circuit; and a large storage charging utility/circuit.

[0116] The small storage charging circuit might be mainly adapted for storing the charge obtained via the plurality of rectifiers by using a plurality of capacitor units as described above. The voltage to current converter circuit may be configured for converting, upon reaching a threshold, the voltage, developed in the small storage charging utility, into current, to be delivered to a large storage charging utility. The large storage charging utility may be configured for accumulating and storing the current arriving from voltage to current conversion in the form of charge in a large storage charging unit for further usage.

[0117] In some embodiments of the present invention, the small storage charging circuit may be designed as a plurality of harvesting units. Each harvesting unit may capture RF energy, rectify and store the energy as a charge on a capacitor unit.

[0118] The plurality of harvesting units may capture plurality of frequency bands, wherein each harvesting unit may be adapted to capture a specific frequency band, or at least two harvesting units may be adapted to capture similar frequency bands different from that/those of other harvesting units.

[0119] The plurality of harvesting circuits may have plurality of capacitor values. In some embodiments, each capacitor unit in the plurality of capacitor units in the small storage charging circuit may include a plurality of capacitors in serial and/or parallel connections (capacitors array).

[0120] The discharging of the small storage charging units may be performed by converting the voltage developed on each of the capacitor units in the plurality of capacitor units to an electric current, by using a voltage to current converter units. The multiple voltage to current converter units of the voltage to current converter circuit may be operable independently; and/or may be operable by a controller that controls all voltage to current converter units or parts thereof. The voltage to current converter units may have voltage thresholds, defining the minimal voltage triggering the conversion of voltage to current. The voltage thresholds of the voltage to current converter units may be different; as well as may be changed by the controller.

[0121] Multiple voltage to current converter units may operate substantially simultaneously, as each unit operates independently and do not interfere to the current converted by other units.

[0122] Each voltage to current converter unit may restrict current flow backwards from the large storage charging circuit to the small storage charging circuit, as the voltage to current converter has the ability to force flow of charge in a certain direction.

[0123] The large storage charging circuit may include a plurality of capacitors in serial and/or parallel connections. In some embodiments, the output of the large storage charging circuit may be connected to one or more of the following: a step up converter; a voltage stabilizer; a battery charging circuit; a capacitor array, and an electric load. In some embodiments, the output of the large storage charging circuit may be either switched or constantly short to the circuit.

[0124] FIG. **11** schematically illustrates an example of a charge collection unit or signal summing unit **900** for accumulating charge corresponding to output of a plurality of rectifiers **911**, **912**, **913** of a rectifying utility of a harvesting system. The signal summing unit **900** includes a small capacitor circuit which in the present example is formed by small capacitor units designated as **921**, **922** and **923**; a voltage to current convertor circuit which in this example is formed by a plurality of voltage to current converters **931**, **932** and **933**; and a large capacitor unit/circuit **940**. The small capacitor units **921**, **922** and **923** are at one end connected to the rectifiers **911**, **912** and **913** respectively and to the voltage to current converters **931**, **932** and **933**, and on the other end are connected to ground **950**.

[0125] Each rectifier receives AC signal from a harvesting antenna unit (or from any other intermediate utility positioned between the antenna unit and the rectifiers), and rectifies the signal. Each of the rectifiers **911**, **912** and **913** is also connected to the respective one of the voltage to current converters **931**, **932** and **933**. The charge of each of the rectifiers **911**, **912** and **913** is being stored, up to a predetermined threshold, as an electric charge in the corresponding one of the small capacitor units **921**, **922** and **923**. Each of the voltage to current converters **931**, **932** and **933** has an intrinsic voltage threshold value that switches the voltage to current converter from a disconnection position (inoperative state) to a connection position (operative state). In the disconnection position of one of the voltage to current converters **931**, **932** and **933**, all current from the corresponding rectifier flows to the corresponding small capacitor unit. Thus, the charge accumulation in the corresponding small capacitor unit increases the voltage on the corresponding small capacitor unit. When voltage threshold is reached, the corresponding voltage to current converter operates as a unidirectional connector, forcing the charge developed in the small capacitor unit to flow directly towards the large capacitor unit **940**.

[0126] It is understood that each of small capacitor units **921**, **922**, and **923** as well as the large capacitor unit **940** may be configured as a single capacitor unit or may include an array of capacitors connected in some combination of serial and parallel connections. It should also be clear that any number of rectifiers may be used, and the number of small capacity units and the number of voltage to current converters is selected accordingly, and that all circuits and devices described in this figure are drawn schematically to emphasize the overall configuration.

1. A system for harvesting electromagnetic energy propagating in surroundings, said system comprising:

an antenna unit configured for receiving external electromagnetic radiation from the surroundings and producing a corresponding electric output;

a harvesting unit comprising at least one energy harvesting circuit each configured and operable for receiving signals indicative of the output of the antenna unit and generating and storing corresponding electric charge, the harvesting circuit comprising: a rectifying unit comprising a plurality of rectifiers each configured and operable to receive AC electric signals and generate corresponding DC electric power; and a charge collection unit configured and operable to receive the plurality of DC electric powers from said rectifying unit and converting and accumulating them into the electric charge presenting harvested energy; and

an input signal adapting circuit having an input connected to the antenna unit and an output connected to the rectifying unit, the input signal adapting circuit being configured and operable for adjusting a predetermined electrical property of the antenna unit and rectifying unit to thereby optimize receipt of the electric output of the antenna unit to the harvesting circuit.

2. A system according to claim **1**, wherein said antenna unit comprises at least two conductive elements positioned in at least two different transmission media being different in at least one of electric and magnetic properties.

3. A system according to claim **1**, wherein said at least two different transmission media include at least two different animate tissues.

4. A system according to claim **1**, wherein said at least two different transmission media include animate tissue and air.

5. A system according to claim **1**, wherein said input signal adapting unit is configured to adjust impedance of the antenna unit to impedance of the rectifying unit.

6. A system according to claim **5**, wherein said input signal adapting unit comprises an impedance matching unit and a filtering unit connected to the impedance matching unit, the impedance matching unit being configured to match between the impedances of the antenna unit and the filtering unit, and the filtering unit being configured and operable for sorting the received RF band propagating in the surrounding into a predefined number of subbands with a predetermined central frequency, band width and strength for each subband, the predefined number of subbands corresponding to a number of the rectifiers in the rectifying unit.

7. A system according to claim **5**, wherein said input signal adjusting unit comprises: an adaptive impedance matching unit configured and operable to controllably adjust impedance of the rectifiers of the rectifying unit to signal intensities of multiple frequency bands received by the antenna unit; and a control unit connectable to the adaptive impedance matching unit and configured and operable operation thereof.

8. A system according to claim **1**, wherein said charge collection unit comprises a signal summing unit comprising a switching topology circuit and a controller, the switching topology circuit comprising a predetermined number of capacitors having relatively small capacitance values and being connected to output of the corresponding number of the rectifiers respectively, and a storage capacitor of a relatively large capacitance value, the switching topology circuit being adapted to controllably switch between the plurality of DC signals received from the plurality of rectifiers respectively with the corresponding plurality of said capacitors of the relatively small capacitance values for power summation and storage of corresponding charge on said capacitor of the relatively large capacitance value.

9. A system according to claim **1**, wherein said charge collection unit comprises a signal summing unit comprising a voltage to current unit comprising a predetermined number of voltage to current conversion circuits having inputs connected to outputs of the corresponding number of the rectifiers respectively, and outputs connected to a storage a capacitor, the voltage to current unit being thereby adapted to convert and sum the plurality of DC signals received from the plurality of rectifiers via the plurality of voltage to current conversion circuits.

10. A system according to claim **1**, comprising a control unit connected to at least one of the input signal adapting unit and the charge collection unit and configured and operable to control operation of the harvesting circuit.

11. A system according to claim **10**, wherein said control unit is connected to at least said charge collection unit which comprises a switching topology circuit comprising a predetermined number of capacitors having relatively small capacitance values and being connected to output of the corresponding number of the rectifiers respectively, and a storage capacitor of a relatively large capacitance value, the switching topology circuit being adapted to controllably switch between the plurality of DC signals received from the plurality of rectifiers respectively with the corresponding plurality of said capacitors of the relatively small capacitance values for power summation and storage of corresponding charge on said capacitor of the relatively large capacitance value.

12. A system according to claim **1**, wherein said harvesting circuit comprises a connection port for connecting output of the charge collection unit to at least one electrical load.

13-16. (canceled)

17. An antenna unit configured and operable for receiving external electromagnetic radiation from surroundings and producing a corresponding output electric signal, said antenna unit comprising at least two conductive elements positioned in at least two different transmission media being different in at least one of electric and magnetic properties, such that received external electromagnetic radiation creates a potential difference between the at least two conductive elements producing an output electric signal, thereby allowing uptake of the external electromagnetic radiation from the surroundings.

18. An antenna unit according to claim **17**, wherein said at least two different transmission media include different animate tissues.

19. An antenna unit according to claim **17**, being attached to an animate body, wherein said at least two different transmission media include animate tissue and air.

20. (canceled)

21. An input signal adapting unit for use with an antenna exposed to electromagnetic radiation of Radio Frequency (RF) band propagating in surroundings, the input signal adapting unit comprising an impedance matching unit and a filtering unit connected to the impedance matching unit, the impedance matching unit being configured to match between impedances of the antenna unit and the filtering unit, and the filtering unit being adapted for sorting the RF band into a predefined number of subbands of a predetermined frequency, bandwidth and strength for each subband.

22. (canceled)

23. A charge collection unit for use in an energy harvesting circuit, the charge collection unit comprising a signal summing unit adapted to receive a plurality of DC electric powers and sum them in the form of an electric charge on a storage capacitor, the signal summing unit comprising at least one of a switching topology unit and a voltage to current unit.

24. A charge collection unit according to claim **23**, wherein the summing unit comprises the switching topology unit and a controller, the switching topology unit comprising a predetermined number of capacitors having relatively small capacitance values and being connectable to output of a corresponding number of rectifiers respectively, and connected to said storage capacitor of a relatively large capacitance value, the switching topology unit being adapted to controllably switch between DC sources received from the rectifiers with said predetermined number of the capacitors for power summation.

25. A charge collection unit according to claim **23**, wherein said voltage to current unit comprises a predetermined number of voltage to current conversion circuits having inputs connectable to outputs of a corresponding number of rectifiers respectively, and outputs connected to the storage capacitor, the voltage to current unit being thereby configured and operable to convert and sum a plurality of DC sources received from the plurality of rectifiers via the voltage to current conversion circuits.

26. An energy harvesting unit comprising at least one energy harvesting circuit, wherein each energy harvesting circuit is configured and operable for receiving signals from an antenna unit and generating and storing corresponding electric charge, the harvesting circuit comprising:

an input signal adapting circuit connectable to output of an antenna unit; a rectifying unit connected to output of the input signal adapting circuit, the rectifying unit comprising a plurality of rectifiers each configured and operable to receive AC electric signals and generate corresponding DC electric power; and a charge collection unit configured and operable to receive the plurality of DC electric powers from said rectifying unit and converting and accumulating them into the electric charge presenting harvested energy;

the harvesting circuit having at least one of the following configurations:

(a) the input signal adapting unit comprises an impedance matching unit and a filtering unit connected to the impedance matching unit, the impedance matching unit being configured to match between impedances of the antenna unit and the filtering unit, and the filtering unit being adapted for sorting the RF band into a predefined number of subbands of a predetermined frequency, bandwidth and strength for each subband; and

(b) the charge collection unit comprises a signal summing unit adapted to receive a plurality of DC electric powers and sum them in the form of an electric charge on a storage capacitor, the signal summing unit comprising at least one of a switching topology unit and a voltage to current unit.

WIDEBAND RECTENNA AND RECTIFYING APPARATUS FOR RECTENNA

CROSS-REFERENCE TO RELATED APPLICATION

[0001] Pursuant to 35 U.S.C. §119(a), this application claims the benefit of earlier filing date and right of priority to Korean Application No. 10-2014-0128530, filed on Sep. 25, 2014, the contents of which is incorporated by reference herein in its entirety.

BACKGROUND OF THE DISCLOSURE

[0002] 1. Field of the Disclosure

[0003] This specification relates to a rectenna, and more particularly, a wideband rectenna.

[0004] 2. Background of the Disclosure

[0005] A rectenna, which converts radio frequency (RF) energy to direct-current (DC) power, is a key component of free-space microwave power transmission (MPT) systems for the application of microwave powered unmanned aerial vehicle (UAVs), space solar power satellite stations (SSPS) and the like. The constraints on the design of MPT systems are the choice of an operating frequency and a system configuration of a transmitter and a receiver.

[0006] Recently, an MPT consisting of an active phased array, a rectenna array system, and a beam controlled system was tested and found to have RF to DC conversion efficiency ($\eta_{RF\text{-}DC}$) of 54% at 1 mW RF input for the unit element and 5.8 GHz. This system, which operates for more than 8 hours, has transmitting and receiving array elements with circular polarization, allowing it to obtain high RF-DC conversion efficiency.

[0007] In order to design a compact rectenna array, a high operating frequency should be chosen to reduce an area of a receiving array aperture. For this reason, there have been some attempts to design rectennas at 35 GHz and 95 GHz. However, there are limitations such as low RF-DC conversion efficiency and high fabricating costs to develop such high power transmitting and receiving systems.

[0008] Therefore, there have been tradeoffs with a compact size and a light weight in terms of choosing an operating frequency for microwave powered aerial vehicle (MPAV) systems, which operate at X-band.

SUMMARY OF THE DISCLOSURE

[0009] Therefore, to obviate the aforementioned drawbacks, an aspect of the detailed description is to provide a wideband rectenna providing high RF-DC conversion efficiency while operating at a wideband, and a rectifying apparatus for rectenna.

[0010] Another aspect of the detailed description is to provide a wideband rectenna for realizing a transmitting and receiving system with a compact size and a light weight, and a rectifying apparatus for rectenna.

[0011] To achieve these and other advantages and in accordance with the purpose of this specification, as embodied and broadly described herein, there is provided a rectenna including a circular-polarized patch antenna having dual slots fed by a microstrip and configured to receive and output a radio frequency (RF) signal, and a rectifying circuit configured to convert for output the RF signal, received by the circular-polarized patch antenna, into a direct current (DC) signal and transfer the DC signal from the antenna to a load, wherein the rectifying circuit comprises at least one radial stub.

[0012] The radial stub may include a first radial stub used for rejecting harmonics of the RF signal, a second radial stub used for impedance matching between the antenna and a rectifying diode, a third radial stub used for the DC power transfer, and a fourth radial stub used for lowering an RF ripple voltage to stably supply the DC power to the load.

[0013] The first radial stub may operate as a band-stop filter.

[0014] The circular-polarized patch antenna may include a first patch substrate with a first patch disposed thereon, a second patch substrate with a second patch disposed thereon, a foam substrate disposed between the first patch substrate and the second patch substrate, and a feed line substrate attached to a lower portion of the second patch.

[0015] The feed line substrate may include H-shaped dual slots, T-shaped feed lines configured to feed the H-shaped dual slots, and a power divider configured to divide power to the feed lines.

[0016] The rectifying circuit may include a harmonic rejecting unit having coupled microstrip lines and a first radial stub and configured to prevent re-radiation of RF harmonics, a matching unit located at an output of the harmonic rejecting unit, having a second radial stub, and configured to perform impedance matching between the antenna and a rectifying diode, a rectifying diode located at an output of the matching unit, a direct current (DC)-pass filter having a third radial stub and configured to attenuate RF output by the rectifying diode to transfer DC power, and a DC return unit having a fourth radial stub and configured to lower a ripple voltage from a signal output by the DC-pass filter so as to supply the DC power stably to the load.

[0017] The harmonic rejecting unit may block noise signals introduced from the antenna.

[0018] The coupled microstrip lines each may operate as a band-pass filter.

[0019] The radial stub may have an angle of circumference of 70°.

[0020] The rectifying circuit may have an operating frequency near 9.5 GHz.

[0021] Also, the present invention provides a rectifying apparatus, including a harmonic rejecting unit having coupled microstrip lines and a first radial stub and configured to prevent re-radiation of radio frequency (RF) harmonics, a matching unit located at an output of the harmonic rejecting unit, having a second radial stub, and configured to perform impedance matching between an antenna and a rectifying diode, a rectifying diode located at an output of the matching unit, a direct current (DC)-pass filter having a third radial stub and configured to attenuate RF output by the rectifying diode to transfer DC power, and a DC return unit having a fourth radial stub and configured to lower a ripple voltage from a signal output by the DC-pass filter so as to supply the DC power stably to a load.

[0022] The first radial stub may be an open-circuited radial stub and operate as a band-stop filter.

[0023] The second radial stub may include two radial stubs symmetric to each other.

[0024] The third radial stub may include a single radial stub, and a pair of radial stubs symmetric to each other.

[0025] The fourth radial stub may include a signal radial stub.

[0026] The harmonic rejecting unit may block noise signals introduced from the antenna.

[0027] The coupled microstrip lines each may operate as a band-pass filter.

[0028] The first radial stub may operate as a band-stop filter.

[0029] The first to fourth radial stubs each may have an angle of circumference of 70°.

[0030] The rectifying apparatus may have an operating frequency near 9.5 GHz.

[0031] A rectenna and a rectifying apparatus for rectenna according to the present invention can provide high RF-DC conversion efficiency while operating at a wideband.

[0032] Also, the use of the rectifying apparatus and the rectenna according to the present invention may allow for implementing a compact system.

[0033] Further scope of applicability of the present application will become more apparent from the detailed description given hereinafter. However, it should be understood that the detailed description and specific examples, while indicating preferred embodiments of the disclosure, are given by way of illustration only, since various changes and modifications within the spirit and scope of the disclosure will become apparent to those skilled in the art from the detailed description.

BRIEF DESCRIPTION OF THE DRAWINGS

[0034] The accompanying drawings, which are included to provide a further understanding of the disclosure and are incorporated in and constitute a part of this specification, illustrate exemplary embodiments and together with the description serve to explain the principles of the disclosure.

[0035] In the drawings:

[0036] FIG. **1** is a configuration view of a general rectenna;

[0037] FIG. **2**A is a disassembled perspective view of a wideband circularly-polarized patch antenna in accordance with one embodiment disclosed herein;

[0038] FIG. **2**B(a) to **2**B(d) are views illustrating feeding circuits of an antenna in accordance with one embodiment disclosed herein;

[0039] FIG. **2**C is a view illustrating a fabricated four-element patch array structure in accordance with one embodiment disclosed herein;

[0040] FIGS. **3**A and **3**B are graphs showing simulation results of a four-element array antenna in accordance with one embodiment disclosed herein;

[0041] FIG. **4**A is a configuration view of a rectifying circuit in accordance with one embodiment disclosed herein;

[0042] FIG. **4**B is a view of a diode equivalent circuit for the circuit of FIG. **4**A;

[0043] FIG. **5**A is a view illustrating a layout of an input harmonic rejecting filter in accordance with one embodiment disclosed herein;

[0044] FIG. **5**B is a graph showing a transmission coefficient characteristic;

[0045] FIG. **6**A is view illustrating a layout of a DC-pass filter in accordance with one embodiment disclosed herein;

[0046] FIG. **6**B is a graph showing a transmission coefficient parameter;

[0047] FIG. **7** is a graph showing conversion efficiency of a DC-pass filter according to a distance from a diode to a capacitor;

[0048] FIG. **8**A is a view illustrating a layout of a DC-return circuit in accordance with one embodiment disclosed herein;

[0049] FIG. **8**B is a graph showing S-parameter;

[0050] FIG. **9**A is a graph showing simulated reflection coefficients of a rectifying circuit disclosed herein according to different input power;

[0051] FIG. **9**B is a graph showing simulated conversion efficiencies of the rectifying circuit disclosed herein according to different input power;

[0052] FIG. **10**A is a view illustrating a simulated value of a reflection coefficient according to different input power;

[0053] FIG. **10**B is a graph showing a simulated RF-DC conversion efficiency;

[0054] FIG. **11**A is a graph showing RF-DC conversion efficiency with respect to actually-measured input power in accordance with one embodiment of the present invention according to different loads;

[0055] FIG. **11**B is a graph showing a converted voltage according to input power;

[0056] FIG. **12**A is a graph showing a measured conversion efficiency in accordance with one embodiment disclosed herein;

[0057] FIG. **12**B is a graph showing a converted voltage.

DETAILED DESCRIPTION OF THE DISCLOSURE

[0058] The present invention may be varied by various ways and have various embodiments, and specific embodiments will be illustrated in the accompanying drawings and described in detail.

[0059] However, this is not to limit the present invention to the specific embodiments, and it should be understood that the present invention includes all the variations, equivalents and replacements belonging to the scope and technical range of the present invention.

[0060] The terms including an ordinal number such as first, second, etc. can be used to describe various elements, but the elements should not be limited by those terms. The terms are used merely for the purpose to distinguish an element from the other element. For example, a first element may be named to a second element, and similarly, a second element may be named to a first element without departing from the scope of right of the invention. The term "and/or" includes any and all combinations of one or more of the associated listed items.

[0061] It will be understood that when an element is referred to as being "connected with" another element, the element can be connected with the other element or intervening elements may also be present. In contrast, when an element is referred to as being "directly connected with" another element, there are no intervening elements present.

[0062] Terms used herein are merely intended to explain specific embodiments, and it should not be understood as limiting the present invention. A singular representation may include a plural representation unless it represents a definitely different meaning from the context. Terms such as "include" or "has" are used herein and should be understood that they are intended to indicate an existence of several characteristics, numbers, steps, operations, components, or combinations thereof, disclosed in the specification, and it is also understood that greater or fewer characteristics, numbers, steps, operations, components, or combinations thereof may likewise be utilized.

[0063] Unless otherwise defined, all terms used herein, including technical or scientific terms, have the same meanings as those generally understood by those with ordinary knowledge in the field of art to which the present invention belongs. Such terms as those defined in a generally used dictionary are to be interpreted to have the meanings equal to the contextual meanings in the relevant field of art, and are not to be interpreted to have ideal or excessively formal meanings unless clearly defined in the present application.

[0064] Hereinafter, description will be given of the preferred embodiments disclosed herein in more detail with reference to the accompanying drawings. In describing the present invention, in order to help understanding of the present invention, the same component on the drawings are designated by the same reference numeral, and repetitive description of the same component will be omitted.

[0065] FIG. **1** is a configuration view of a general rectenna.

[0066] As illustrated in FIG. **1**, a general rectenna may include an antenna **110**, and a rectifying circuit **120**. A load **130** may be connected to the rectenna, more particularly, to an output of the rectifying circuit **120**.

[0067] The rectifying circuit **120** may include a harmonic rejecting filter **121**, a matching circuit **122**, a diode **123** and a direct-current (DC) pass filter **124**.

[0068] Here, the non-linear characteristic of the diode **123** may generate unwanted harmonic signals that propagate backward to the antenna **110** and forward to the load **130**. Therefore, the harmonic rejecting filter **121**, the DC-pass filter **124** and the matching circuit **122** should be carefully designed to obtain an optimized RF-DC conversion efficiency ($\eta_{RF\text{-}DC}$).

[0069] Hereinafter, description will be given of a patch antenna structure according to the present invention.

[0070] FIG. **2**A is a disassembled perspective view of a wideband circularly-polarized patch antenna in accordance with one embodiment disclosed herein.

[0071] FIG. **2**A illustrates an antenna element which has a resonance cavity resulting from first and second patch substrates **210** and **230** having two layered square patches, and foam disposed between the substrates **210** and **230**.

[0072] Also, a substrate **240** having a vertical slot and a horizontal slot may be disposed between the second patch substrate **230** and a feed line substrate **250**. The vertical slot and the horizontal slot provide orthogonal excitation to the cavity.

[0073] Circular polarization is obtained by a Wilkinson power divider and a delay line with a 90-degree phase difference between dual slots.

[0074] That is, the patch antenna can be designed to obtain broadband and circular-polarization characteristics using H-shaped slots and T-shaped feed lines that are stacked in a multi-layer substrate structure.

[0075] As illustrated in FIG. **2**A, the patch antenna according to the one embodiment disclosed herein may be configured in a manner that the feed line substrate **250** for a feed line **260** is 0.38 mm thick, the substrate **230** for a lower patch is 0.64 mm thick, the substrate **220** for foam is 0.1 mm thick, and the substrate **210** for an upper patch is 0.25 mm thick.

[0076] Also, relative dielectric constants ($\in_r$) of the substrate **250** for the feed line, the substrate **230** for the lower patch, the substrate for the foam and the substrate **210** for the upper patch may be 3.5, 2.17, 1.02, and 2.17, respectively.

[0077] Here, the substrates for the dual patches and the foam may be implemented with the low relative dielectric constants so as to obtain maximum radiation efficiency and wide bandwidth, while the feed line substrate may be implemented with the relatively higher relative dielectric constant than those of the substrates for the dual patches and the foam so as to improve maximum feed efficiency.

[0078] The resonance frequency of the cavity is mainly determined by a side length of a square patch. Sizes of the upper patch and the lower patch can be designed to have a small difference in order to obtain the wideband characteristics of the antenna element.

[0079] For example, the lengths of the upper square patch and the lower square patch may be 9.64 mm and 8.51 mm, respectively.

[0080] FIG. **2**B(a) to **2**B(d) are views illustrating feeding circuits of an antenna in accordance with one embodiment disclosed herein.

[0081] In detail, FIG. **2**B(a) illustrates an H-shaped slot **241** used for a wideband circular-polarized patch antenna, FIG. **2**B(b) and FIG. **2**B(c) illustrate T-shaped feed lines **261** and **262**, and FIG. **2**B(d) illustrates a power divider **263**. Optimized geometrical parameters are illustrated in FIG. **2**B(a) to FIG. **2**B(d).

[0082] Here, a T-shaped microstrip open stub may be electrically connected to ports **2** and **3** of the power divider **263** illustrated in FIG. **2**B(d), respectively. The T-shaped feed line may be designed to occupy a smaller space than the general microstrip open stub with a length of λ/4. These stubs feed the H-shaped dual slots **241**.

[0083] The power divider **263** may include a delay line **1** which extends more along one of the port **2** or the port **3** to be longer than the other, in order to create a 90-degree phase difference between the port **2** and the port **3**.

[0084] Each port of the power divider **263** disclosed herein preferably has characteristic impedance of 65Ω instead of 50Ω, in order to provide an enough array spacing by reducing a width of the divider **263** having higher impedance.

[0085] FIG. **2**C is a view illustrating a fabricated four-element patch array structure in accordance with one embodiment disclosed herein.

[0086] As illustrated in FIG. **2**C, an actually-fabricated four-element patch array preferably has an element spacing of 0.8λ. Here, λ is preferably the wavelength at 9.5 GHz.

[0087] The patch array structure of FIG. **2**C may have a Wilkinson power divider to feed the four patches. A patch cavity and a microstrip feed circuit are isolated by a conductor plane having the H-shaped slots, which may result in the merit of easy fabrication of a rectifier circuit on a feeding circuit layer for a large rectenna array.

[0088] FIG. **3** is a graph showing simulation results of a four-element array antenna in accordance with one embodiment disclosed herein.

[0089] In FIG. **3**A, simulated and measured reflection coefficients for the four-element array antenna are indicated with S_{11} with respect to a frequency.

[0090] The measured S_{11} has the lowest value at around 9.5 GHz, and a wideband characteristic in the range from −10 dB over 2 GHz, which is similar to the wideband characteristic of the simulated S_{11}.

[0091] The measured lowest value is −34 dB at 9.3 GHz.

[0092] FIG. **3**B is a graph showing gains of a fabricated four-element array antenna in accordance with one embodiment of the present invention.

[0093] The graph of FIG. **3**B shows simulated and measured gains of the four-element array antenna at 9.5 GHz.

[0094] FIG. **3**B shows horizontal radiation characteristics of the gains. Because the patch array is symmetric, vertical characteristics are similar to the horizontal characteristics.

[0095] Meanwhile, it can be noticed that the measured gain of the four-element array antenna is in a good agreement with the simulated gain. The measured and simulated gains are 11.2 dBi and 12.7 dBi, respectively.

[0096] It can also be understood that a circular-polarization (CP) characteristic of the four-element array antenna is measured in an axial ratio of 1.1 dB at a boresight angle of the antenna.

[0097] FIG. **4**A is a configuration view of a rectifying circuit in accordance with one embodiment disclosed herein, and FIG. **4**B is a view of a diode equivalent circuit for the circuit of FIG. **4**A.

[0098] A rectifying circuit **300** illustrated in FIG. **4**A is an X-band rectifying circuit. A rectifier designed according to one embodiment disclosed herein is compact because a single X-band rectenna is used for a large rectenna array application with a device spacing of 0.8λ. For this application, a feeding network of the antenna and the rectifier are designed using a microstrip line structure.

[0099] The rectifier (for example, a half-wave rectifier) may include a harmonic rejecting unit **310**, a matching unit **320**, a rectifying diode **323**, a DC-patch unit **330** and a DC return unit.

[0100] Here, the diode **323** is one of the most critical components for obtaining high RF-DC conversion efficiency (η_{RF-DC}) in the rectifying circuit **300**. Here, the RF-DC conversion efficiency (η_{RF-DC}) of the rectifying circuit **300** may be defined as the following Formula 1.

$$\eta_{RF-DC} = \frac{P_{DC}}{P_{RF}} = \frac{V_{DC}^2 / R_L}{P_{RF}}$$ [Formula 1]

[0101] Here, P_{DC}, P_{RF}, V_{DC} and R_L denote converted DC power, received RF power, converted DC voltage and load impedance, respectively.

[0102] The rectifying diode **323** of the rectenna as illustrated in FIG. **4**A, as aforementioned, is the most important component in the design of the rectifying circuit **300**. Therefore, the rectenna antenna according to the present invention is preferably set by several conditions to be explained later.

[0103] Conditions for the diode according to the present invention include a high breakdown voltage V_{br} which is related to efficiency of high input power, a low forward voltage V_f which is related to capability of detecting (capturing) small signals, low series resistance R_s which is related to overall efficiency of the rectifier, and low junction capacitance C_j which is related to an operation bandwidth.

[0104] The diode disclosed herein may preferably be a packaged Schottky barrier diode of type HSMS-8101 from Avago Technologies, for example. Since the diode optimally operates over a frequency range from 10 GHz to 14 GHz, it is suitable for use at 9.5 GHz.

[0105] Referring to FIG. **4**B which shows a diode equivalent circuit for the circuit of FIG. **4**A, the series resistance voltage R_s is 6 (R_s=6), the junction capacitance C_j is 0.17 pF (C_j=0.17 pF), the forward voltage V_f is in the range of 0.25 to 0.35 V, and the breakdown voltage V_{br} is greater than −4V (V_{br}<−4V). The junction capacitance C_j is variable according to operating conditions.

[0106] Under these conditions, if it is assumed that a 9.5 GHz operating frequency, 10 mW input power and 100Ω load are provided, upon having 50Ω source impedance, a calculated input impedance of the diode using a circuit simulation is (22-j20) Ω. The impedance difference between the antenna and the diode causes a reduction of power transfer and diode efficiency. Therefore, in order to maximize the RF power transfer from the antenna to the diode, the impedance matching circuit **320** may be designed as illustrated in FIG. **4**A.

[0107] That is, because the input impedance of the diode changes according to the operating frequency, the RF input power and the load resistance, the matching circuit **320**, as illustrated in FIG. **4**A, is preferably designed using two radial stubs for wideband operations.

[0108] Here, the radial stubs for impedance matching between the antenna and the diode **323** preferably have an angle of circumference of 70°.

[0109] In general, non-linearity of the diode generates higher-order harmonics, which causes the reduction of RF-DC conversion efficiency. Thus, the harmonic rejecting filter **310** and the DC-pass filter **330** are necessary to suppress the higher-order harmonics.

[0110] FIG. **5**A is a view illustrating a layout of an input harmonic rejecting filter in accordance with one embodiment disclosed herein, and FIG. **5**B is a graph showing transmission coefficient S_{21} characteristics of the input harmonic rejecting filter.

[0111] The harmonic rejecting filter **310** illustrated in FIG. **5**A may include coupled microstrip lines **311** and a radial stub **312**.

[0112] The harmonic rejecting filter **310** prevents re-radiation of RF harmonics from the diode **323** and blocks unwanted noise signals received from the antenna.

[0113] The transmission coefficient S_{21} may be analyzed using a simulator (for example, an advanced design system (ADS) momentum simulator). The coupled microstrip bandpass filter **311** of the harmonic rejecting filter **310** are centered at 9.5 GHz operating frequency with −3 dB, and has 7.3 GHz bandwidth.

[0114] In other words, the harmonic rejecting filter which includes an open-circuited radial stub **312** operating as a band-stop filter and the band-pass filter **311**, as illustrated in FIG. **5**B, attenuates a first harmonic frequency near 19 GHz and a second harmonic frequency near 28.5 GHz, so as to lower the transmission coefficients S_{21} to −26.6 dB and −16.5 dB, respectively.

[0115] Here, the radial stub **312** for rejecting the harmonics of the RF signals, as illustrated in FIG. **5**A, preferably has an angle of circumference of 70°.

[0116] FIG. **6**A is view illustrating a layout of a DC-pass filter in accordance with one embodiment disclosed herein, and FIG. **6**B is a graph showing a transmission coefficient S_{21} characteristic of the DC-pass filter.

[0117] The DC-pass filter according to the one embodiment disclosed herein attenuates the RF so as to transfer only DC power to the load. The DC-pass filter may be positioned at an output of the diode **323**. The DC-pass filter **330** includes a single radial stub **331** and a pair of radial stubs **332** symmetric to each other, and attenuates the transmission coefficient parameters S_{21} of fundamental, second and third harmonics to be lower than 15 dB, namely, down to −26 dB, −18.8 dB and −25.5 dB, respectively.

[0118] Here, the single radial stub **331** for DC power transfer or the pair of radial stubs **332** for lowering an RF ripple voltage, as illustrated in FIG. **6**A, preferably have an angle of circumference of 70°.

[0119] FIG. **7** is a graph showing conversion efficiency of a DC-pass filter according to a distance from a diode to a capacitor.

[0120] Here, a distance from the diode **323** to a capacitor C_L may be indicated with a reference numeral d, as illustrated in FIG. **4**A.

[0121] In the rectifying circuit **300**, a capacitor which is connected in parallel to the load lowers a ripple voltage and supplies DC power stably to the load.

[0122] As illustrated in FIG. **7**, it can be understood that the DC-pass filter **330** maintains the RF-DC conversion efficiency almost to be a constant with respect to the distance which changes.

[0123] On the other hand, in case of an operation without the DC-pass filter **330** disclosed herein, it can be noticed that the RF-DC conversion efficiency is drastically degraded and an optimum length for the maximum RF-DC conversion efficiency is present.

[0124] Therefore, the DC-pass filter **330** disclosed herein may be a key component for the stable operation of the rectifying circuit **300**.

[0125] FIG. **8**A is a view illustrating a layout of a DC-return unit in accordance with one embodiment disclosed herein, and FIG. **8**B is a graph showing S-parameter.

[0126] The DC return unit **340** is used to prevent re-reflection of harmonics generated by the diode **323** when a reverse current flows into the diode **323**. The DC return unit **340** may reject a countercurrent from the ground (port **3** of FIG. **8**A) back to the rectifying circuit and prevent RF re-reflection to the antenna.

[0127] The DC return unit **340** may function as a band-stop filter to block an X-band transmission between the ground (port **3**) and ports **1** and **2**.

[0128] On the other hand, the RF transmission from the port **1** to the port **2** at the frequency ranging from 3.2 to 13.5 GHz (3 dB band-pass region) is not affected by the ground.

[0129] Here, as illustrated in FIG. **8**A, the DC return unit **340** may further include a radial stub between the ground (port **3**) and the ports **1** and **2**. To lower an RF ripple voltage and supply DC power stably to the load, the radial stub preferably has an angle of circumference of 70°.

[0130] FIG. **9**A is a graph showing simulated reflection coefficients of a rectifying circuit disclosed herein according to different input power, and FIG. **9**B is a graph showing simulated conversion efficiencies of the rectifying circuit disclosed herein according to different input power.

[0131] FIGS. **9**A and **9**B show calculated S_{11} and RF-DC conversion efficiency for the estimation of the rectifying circuit performance under various operation conditions.

[0132] The RF-DC conversion efficiency ($\eta_{RF\text{-}DC}$) was calculated according to Formula 1, as aforementioned, with respect to load resistance of 50Ω to 1000Ω and input power of 10 dBm, 11 dBm and 12.5 dBm.

[0133] Since the input impedance of the diode changes according to the operation conditions, as illustrated in FIGS. **9**A and **9**B, the rectifying circuit has been optimized with respect to the load resistance according to the input power at 9.5 GHz. When the input power is 12.5 dBm and the load resistance is 400Ω, the maximum efficiency and voltage are 71% and 2.25 V, respectively.

[0134] Because the impedances of the diode and each of the components of the rectifying circuit vary according to changes of the operation conditions, it is difficult to design the rectifying circuit for wideband operation. To overcome the difficulty in the present invention, the components of the rectifying circuit were designed using radial stubs to allow for operations over wideband frequencies.

[0135] FIGS. **10**A and **10**B are graphs showing simulation results for S_{11} and RF-DC conversion efficiency according to a frequency and different input power.

[0136] According to the simulation results illustrated in FIG. **10**A, it can be understood that the reflection coefficient S_{11} is lower than −10 dB in a frequency range from 8.8 to 9.9 GHz. Also, it can be checked in FIG. **10**B that the RF-DC conversion efficiency is higher than 50% in a frequency range from 9.1 to 10.2 GHz with respect to input power of 12.5 dBm.

[0137] FIGS. **11**A and **11**B are graphs showing RF-DC conversion efficiency and a converted voltage with respect to actually-measured input power according to different loads.

[0138] It can be understood that the overall tendency of the measured RF-DC conversion efficiency with respect to the input power illustrated in FIG. **11**A is similar to the simulation results. However, an optimal condition for the maximum RF-DC conversion efficiency is slightly different. The simulated maximum RF-DC conversion efficiency is 71% with respect to 12.5 dBm under the load of 40Ω, but the measured maximum RF-DC conversion efficiency is 71.9% with respect to 17 dBm under the load of 300Ω. It is obvious from the measurement results that the diode and the rectifying circuit according to the present invention can be used at higher input power than the simulated value.

[0139] Referring to FIG. **11**B, it can also be noticed that the converted DC voltage increases as the input power increases and the DC voltage at the maximum efficiency is 3.2 V.

[0140] Compared to the conventional conversion circuit which has exhibited 63.2% efficiency at 8.51 GHz or 21% efficiency at 9.3 GHz, it can be noticed that the efficiency of the RF-DC conversion circuit according to the present invention is higher than those of such conventional circuits at the X-band frequency.

[0141] FIGS. **12**A and **12**B are graphs showing measured conversion efficiency and converted voltage in accordance with one embodiment disclosed herein.

[0142] As illustrated in FIG. **12**A, it can be seen that the rectifying circuit disclosed herein has the maximum efficiency of 71.9% and keeps having efficiency more than 50% over 1 GHz frequency bandwidth.

[0143] The rectifying circuit according to the present invention is optimized compactly with dimensions of 35 mm by 21 mm (35×21) at 9.5 GHz, so as to be applied to a large rectenna array system.

[0144] The present invention has been described with reference to the foregoing embodiments, but it can be understood that various modifications and changes can be obtained from the present invention without departing from the scope of the present invention as defined in the appended claims.

What is claimed is:

1. A rectenna comprising:

a circular-polarized patch antenna configured to receive a radio frequency (RF) signal; and

a rectifying circuit configured to convert for output the RF signal, received by the circular-polarized patch antenna, into a direct current (DC) signal and transfer the DC signal from the antenna to a load,

wherein the rectifying circuit comprises at least one radial stub.

2. The rectenna of claim **1**, wherein the radial stub comprises at least one of a first radial stub used for rejecting harmonics of the RF signal, a second radial stub used for impedance matching between the antenna and a rectifying diode, a third radial stub used for the DC power transfer, and a fourth radial stub used for lowering an RF ripple voltage to stably supply the DC power to the load.

3. The rectenna of claim **2**, wherein the first radial stub operates as a band-stop filter.

4. The rectenna of claim **1**, wherein the circular-polarized patch antenna comprises:

a first patch substrate with a first patch disposed thereon;

a second patch substrate with a second patch disposed thereon;

a foam substrate disposed between the first patch substrate and the second patch substrate; and

a feed line substrate attached to a lower portion of the second patch.

5. The rectenna of claim **4**, wherein the feed line substrate comprises:

H-shaped dual slots;

T-shaped feed lines configured to feed the H-shaped dual slots; and

a power divider configured to divide power to the feed lines.

6. The rectenna of claim **1**, wherein the rectifying circuit comprises:

a harmonic rejecting unit configured to prevent re-radiation of RF harmonics, the harmonic rejecting unit having coupled microstrip lines and a first radial stub;

a matching unit located at an output of the harmonic rejecting unit and configured to perform impedance matching between the antenna and a rectifying diode, the matching unit having a second radial stub;

a rectifying diode located at an output of the matching unit;

a direct current (DC)-pass filter having a third radial stub and configured to attenuate RF output by the rectifying diode to transfer DC power; and

a DC return unit having a fourth radial stub and configured to lower a ripple voltage from a signal output by the DC-pass filter so as to supply the DC power stably to the load.

7. The rectenna of claim **6**, wherein the harmonic rejecting unit blocks noise signals introduced from the antenna.

8. The rectenna of claim **6**, wherein the coupled microstrip lines each operates as a band-pass filter.

9. The rectenna of claim **1**, wherein the radial stub has an angle of circumference of 70°.

10. The rectenna of claim **1**, wherein the rectifying circuit has an operating frequency near 9.5 GHz.

11. A rectifying apparatus comprising:

a harmonic rejecting unit having coupled microstrip lines and a first radial stub and configured to prevent re-radiation of radio frequency (RF) harmonics;

a matching unit located at an output of the harmonic rejecting unit and configured to perform impedance matching between an antenna and a rectifying diode, the matching unit having a second radial stub;

a rectifying diode located at an output of the matching unit;

a direct current (DC)-pass filter having a third radial stub and configured to attenuate RF output by the rectifying diode to transfer DC power; and

a DC return unit having a fourth radial stub and configured to lower a ripple voltage from a signal output by the DC-pass filter so as to supply the DC power stably to a load.

12. The apparatus of claim **11**, wherein the coupled microstrip lines each operates as a band-pass filter.

13. The apparatus of claim **11**, wherein the first radial stub is an open-circuited radial stub and operates as a band-stop filter.

14. The apparatus of claim **11**, wherein the second radial stub comprises two radial stubs symmetric to each other.

15. The apparatus of claim **11**, wherein the third radial stub comprises a single radial stub, and a pair of radial stubs symmetric to each other.

16. The apparatus of claim **11**, wherein the fourth radial stub comprises a signal radial stub.

17. The apparatus of claim **11**, wherein the harmonic rejecting unit blocks noise signals introduced from the antenna.

18. The apparatus of claim **11**, wherein the first radial stub operates as a band-stop filter.

19. The apparatus of claim **11**, wherein the first to fourth radial stubs each has an angle of circumference of 70°.

20. The apparatus of claim **11**, wherein the rectifying apparatus has an operating frequency near 9.5 GHz.

(57) **ABSTRACT**

A cloaking device includes cloaking region boundary planes oriented non-planar to each other, each of the cloaking region boundary planes having an outward facing mirror surface and an inward facing opaque surface. The cloaking device includes a cloaking region bounded at least partially by the inward facing opaque surfaces of the cloaking region boundary planes. Half mirrors are spaced apart and generally parallel to the outward facing mirror surfaces such that a half mirror is spaced apart and generally parallel to each outward facing mirror surface. Light from an object on an object-side of the cloaking device is directed around an article within the cloaking region and forms an image on an image-side of the cloaking device such the article appears transparent to an observer looking towards the object.

APPARATUSES AND METHODS FOR MAKING AN OBJECT APPEAR TRANSPARENT

RELATED APPLICATION

[0001] This application claims the benefit of U.S. Provisional Patent Application Ser. No. 62/291,920 filed Feb. 5, 2016, the entirety of which is incorporated herein by reference.

TECHNICAL FIELD

[0002] The present specification generally relates to apparatuses and methods for making an object appear transparent and, more specifically, to cloaking devices for pillars of vehicles and methods for making pillars of vehicles appear transparent.

BACKGROUND

[0003] Studies on cloaking devices that appear to make a pillar of a vehicle transparent have been published. Such studies disclose the use of metamaterials or the use of video cameras in combination with a display screen to allow an occupant of a vehicle to ostensibly "see" though the vehicle pillar, thereby reducing blind spots in the vehicle. However, metamaterials and video technology use complicated material designs and equipment.

[0004] Accordingly, a need exists for alternative devices that appear to make a pillar of a vehicle transparent.

SUMMARY

[0005] In one embodiment, a cloaking device includes cloaking region (CR) boundary planes oriented non-planar to each other and each of the CR boundary planes has an outward facing mirror surface and an inward facing opaque surface. The cloaking device includes a CR at least partially bounded by the inward facing opaque surfaces of the CR boundary planes. The cloaking device includes half mirrors spaced apart and generally parallel to the outward facing mirror surfaces such that a half mirror is spaced apart and generally parallel to each outward facing mirror surface. An article positioned within the CR is not visible outside of the CR and light reflected from an object on one side of the cloaking device is redirected around the CR and the article positioned within the CR, and forms an image of the object on another side of the cloaking device.

[0006] According to another embodiment, a cloaking device for cloaking an article of a vehicle includes a cloaking assembly with an object-side, an image-side and at least two CR boundary planes positioned at least partially between the object-side and the image-side. The at least two CR boundary planes are positioned non-planar to each other and each of the at least two CR boundary planes have an outward facing mirror surface and an inward facing opaque surface. A CR is bounded by the inward facing opaque surfaces of the at least two CR boundary planes and a vehicle article positioned within the CR is not visible from outside the CR. The cloaking assembly has at least two half mirrors positioned at least partially between the object-side and the image-side. Each of the at least two half mirrors are spaced apart and generally parallel to one of the outward facing mirror surfaces such that a half mirror is spaced apart and generally parallel to each outward facing mirror surface. Light from an object located on the object-side of the cloaking assembly, and obscured by the vehicle article positioned within the CR is redirected around the CR, and forms an image of the object on the image-side of the cloaking assembly such that the vehicle article appears transparent to an observer looking in a direction towards the object.

[0007] In embodiments, the cloaking assembly has four CR boundary planes and four half mirrors. The four CR boundary planes are oriented generally orthogonal to each other, the CR is bounded by the four CR boundary planes, and each of the half mirrors are spaced apart and generally parallel to one of the outward facing mirror surfaces such that a half mirror is spaced apart and generally parallel to each outward facing mirror surface. Each of the half mirrors may be selected from a p-polarization half mirror or an s-polarization half mirror. Light reflected from the object located on the object-side of the cloaking assembly passes through the cloaking assembly by reflecting off of a first outward facing mirror surface, a first half mirror oriented generally parallel to the first outward facing mirror surface, a second half mirror oriented generally orthogonal to the first half mirror and a second outward facing mirror surface oriented generally parallel to the second half mirror. Light that passes through the cloaking assembly forms an image of the object on the image-side of the cloaking assembly.

[0008] In embodiments, the cloaking device with the cloaking assembly has an end surface oriented non-planar to a half mirror. Light from an item located adjacent to the end surface passes through the cloaking assembly and forms an image of the item on the image side of the cloaking assembly.

[0009] These and additional features provided by the embodiments described herein will be more fully understood in view of the following detailed description in conjunction with the drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

[0010] The embodiments set forth in the drawings are illustrative and exemplary in nature and not intended to limit the subject matter defined by the claims. The following detailed description of the illustrative embodiments can be understood when read in conjunction with the following drawings, where like structure is indicated with like reference numerals and in which:

[0011] FIG. **1** schematically depicts a top view of a cloaking device according to one or more embodiments described and illustrated herein;

[0012] FIG. **2** schematically depicts top isolated views of four cloaking device components of the cloaking device of FIG. **1** according to one or more embodiments described and illustrated herein;

[0013] FIG. **3** schematically depicts a top perspective view of the cloaking device of FIG. **1** with a first object on one side of the cloaking device and a second object within a cloaking region (CR) of the cloaking device;

[0014] FIG. **4** schematically depicts a side view of the cloaking device of FIG. **3** with the first object on one side of the cloaking device and the second object within the CR of the cloaking device;

[0015] FIG. **5** schematically depicts a top view of a cloaking device according to one or more embodiments described and illustrated herein;

[0016] FIG. **6** schematically depicts a top perspective view of the cloaking device of FIG. **5** with a first object on one side of the cloaking device and a second object and a third object within a CR of the cloaking device;

[0017] FIG. **7** schematically depicts a side view of the cloaking device of FIG. **6** with the first object on one side of the cloaking device and the second object and the third object within the CR of the cloaking device;

DETAILED DESCRIPTION

[0030] A cloaking device is provided. The cloaking device may have an object-side, an image-side and a cloaking region (CR) boundary plane having an outward facing mirror surface and an inward facing opaque surface. A CR is at least partially bounded by the inward facing opaque surface of the CR boundary plane and a half mirror is spaced apart and generally parallel to the outward facing mirror surface. The half mirror may be a p-polarization half mirror or an s-polarization half mirror. In embodiments, an article, e.g. an A-pillar of a vehicle, a B-pillar of a vehicle or a C-pillar of a vehicle, is positioned within the CR and light from an object located on the object-side of the cloaking device and obscured by the CR is redirected around the CR and the article and forms the image of the object on the image-side of the cloaking device such that the article appears transparent. Various embodiments of cloaking devices and methods for using the same will be described in further detail herein with specific reference to the appended drawings.

[0031] FIG. **1** generally depicts one embodiment of a cloaking device. The cloaking device includes a cloaking region (CR) that is at least partially bounded by at least two CR boundary planes that are non-planar to each other. Each of the two CR boundary planes has an outward facing mirror surface and an inward facing opaque surface. Spaced apart and oriented generally parallel to each of the CR boundary planes is a half mirror (e.g., a polarizing half mirror) that allows p-polarized light to pass through and s-polarized light to be reflected or, alternatively, allows s-polarized light to pass through and p-polarized light to be reflected. Referring to the coordinate system in the figure, portions of a target object are located directly behind the CR in the +Y direction (obscured portions of the object which are otherwise not visible through the CR) and portions of the target object are located outside or beyond the CR in the +Y direction (visible portions of the object). Light rays (light) from the obscured portions of the target object travel in the −Y direction and are incident on a first outward facing mirror surface. The first outward facing mirror surface reflects the incident light from the obscured portions of the target object in the +X direction to a first half mirror that is spaced apart and oriented generally parallel to the first outward facing mirror surface. One mode of polarized light (e.g., p-polarized light) from the light reflected from the first outward facing mirror surface passes through the first half mirror (continues traveling in the +X direction), while another mode of polarized light (e.g. s-polarized light) is reflected by the first half mirror in the −Y direction. The polarized light reflected in the −Y direction by the first half mirror is reflected into the −X direction by a second half mirror. The polarized light reflected into the −X direction by the second half mirror is reflected in the −Y direction by a second outward facing mirror surface that is spaced apart and oriented generally parallel to the second half mirror. An observer looking at the cloaking device in the +Y direction will see the reflection of the polarized light by the second outward facing mirror surface, i.e. polarized light originating from light from obscured portions of the target object will be visible to a human eye located on an opposite side of the CR from the obscured portions of the target object. Also, light reflected from an article positioned within the CR (i.e., the cloaked article) is not transmitted through the inward facing opaque surfaces and is not seen by the observer looking at the cloaking device in the +Y direction. That is, the cloaking device effectively redirects light from the obscured portions of the target object around the CR such that the light from the target object appears to pass through the cloaked article giving the visual impression that the cloaked article is not present. Light from the visible portions of the target object travel in the −Y direction and are incident on the first half mirror. One mode of the incident light (e.g., s-polarized light) is reflected in the +X direction by the first half mirror and another mode of the incident light (e.g. p-polarized light) is transmitted through the first half mirror and continues traveling in the −Y direction. The transmitted polarized light traveling in the −Y direction reaches the second half mirror and is transmitted through the second half mirror. An observer looking at the cloaking device in the +Y direction will see the transmitted polarized light traveling in the −Y direction, i.e. polarized light originating from light from visible portions of the target object will be visible to a human eye located on an opposite side of the cloaking device from the visible portions of the target object. Accordingly, an individual will see the entire target object, both obscured portions and visible portions, that is located on the opposite side of the CR (and thus on the opposite side of a cloaked article) giving the visual impression that the cloaked article is transparent.

[0032] Referring now to FIGS. **1**-**2**, embodiments of a cloaking device include a cloaking assembly **10** with four CR boundary planes **118**, **128**, **138**, **148**. The CR boundary planes **118**, **128**, **138**, **148** located adjacent to each other are non-planar to each other. In embodiments, opposing CR boundary planes **118**, **148** and **128**, **138** may be oriented parallel to each other and adjacent CR boundary planes **118**, **128**, **138**, **148** may be oriented orthogonal to adjacent CR boundary planes, e.g. CR boundary plane **118** is oriented orthogonal to adjacent CR boundary planes **138**, **128**, CR boundary plane **128** is oriented orthogonal to adjacent CR boundary planes **118**, **148**, etc. Each of the four CR boundary planes have an outward facing mirror surface **118***a*, **128***a*, **138***a*, **148***a*, respectively, and an inward facing opaque surface **118***b*, **128***b*, **138***b*, **148***b*, respectively. The outward facing mirror surfaces **118***a*, **128***a*, **138***a*, **148***a*, can be made from omnidirectional photonic crystals or mirrors such that approximately 100% (+/−10%) of light incident on the outward facing mirror surfaces is reflected from the outward facing mirror surfaces. Accordingly, the term “mirror surface” used herein refers to a surface that reflects approximately 100% (+/−10%) of all modes of light (e.g. s-polarized light and p-polarized light) incident on the mirror surface. In embodiments, the CR boundary planes **118**, **128**, **138**, **148** form a CR **200** bound at least partly by the inward facing opaque surfaces **118***b*, **128***b*, **138***b*, **148***b*. The four CR boundary planes **118**, **128**, **138** **148**, have a height ‘h’ (FIG. **4**) in the Z direction of the coordinate axes in the figures and light reflected or transmitted within the CR **200** does not pass through the inward facing opaque surfaces **118***b*, **128***b*, **138***b*, **148***b*. Accordingly, an article (e.g., a cloaked article) located within the CR **200** is not visible to an observer viewing the cloaking assembly **10** in the +Y direction.

[0033] Still referring to FIGS. **1** and **2**, spaced apart and oriented generally parallel (within +/−2°) to each of the four CR boundary planes **118**, **128**, **138** **148**, are half mirrors **115**, **125**, **135**, **145**, respectively. The half-mirrors **115**, **125**, **135**, **145** reflect a specific mode of visible light. Specifically, each of the half mirrors **115**, **125**, **135**, **145**, can be an s-polarizer half mirror or a p-polarizer half mirror. The half mirrors **115**, **125**, **135**, **145**, can be in the form of a diffraction grating or thin film polarizer that reflects the s-mode of visible light and allows the p-mode of visible light to pass through (a p-polarization diffraction grating or thin film), or in the alternative, reflects the p-mode of visible light and allows the s-mode of the visible light to pass through (an s-polarization diffraction grating or thin film). It should be appreciated that the half mirrors **115**, **125** are both s-polarizer half mirrors or p-polarizer half mirrors and the half mirrors **135**, **145** are both s-polarizer half mirrors or p-polarizer half mirrors, i.e. the half mirrors **115**, **125** may be s-polarizer mirrors and the half mirrors **135**, **145** may be p-polarizer half mirrors; the half mirrors **115**, **125** may be p-polarizer mirrors and the half mirrors **135**, **145** may be s-polarizer half mirrors; or all of the half mirrors **115**, **125**, **135**, **145** may be s-polarizer half mirrors or p-polarizer half mirrors.

[0034] The four CR boundary planes **118**, **128**, **138** **148**, and the corresponding half mirrors **115**, **125**, **135**, **145**, may be part of four cloaking assembly components **110**, **120**, **130**, **140**, respectively. Each cloaking assembly component **110**, **120**, **130**, **140**, has an outward facing surface **112**, **122**, **132**, **142**, respectively, an inward facing surface **114**, **124**, **134**, **144**, respectively, an outer end surface **116**, **126**, **136**, **146**, respectively, and an inner side surface defined by the inward facing opaque surface **118***b*, **128***b*, **138***b*, **148***b*, respectively. The outward facing surfaces **112**, **132** form an object-side **102** of the cloaking device and the outward facing surfaces **122**, **142** form an image-side **104** of the cloaking device. One or more optical filters **125***a*, **125***b* may be positioned on or adjacent to the outward facing surface **122** and one or more optical filters **145***a*, **145***b* may be positioned on or adjacent to the outward facing surface **142**. The optical filter **125***a* is positioned to the right (+X direction) of the half-mirror **125**, the optical filter **125***b* is positioned to the left (−X direction) of the half-mirror **125**, the optical filter **145***a* is positioned to the left (−X direction) of the half-mirror **145**, and the optical filter **145***b* is positioned to the right (+X direction) of the half-mirror **145**. The one or more optical filters **125***a*, **125***b*, **145***a*, **145***b*, may be quarter-wave plates that convert linearly polarized light into circularly polarized light, or in the alternative, the one or more optical filters **125***a*, **125***b*, **145***a*, **145***b*, may be a quarter-wave plate and a linear polarizer that convert linearly polarized light of one mode, e.g., s-mode or p-mode, into circularly polarized light, and then convert the circularly polarized light into a different linearly polarized mode, e.g., p-mode or s-mode, respectively.

[0035] The CR boundary planes **118**, **138**, are oriented at an angle θ_1 relative to the outward facing surfaces **112**, **132**, respectively, and the CR boundary planes **128**, **148** are oriented at an angle β_1 relative to the outward facing surfaces **122**, **142**, respectively. In embodiments, the angle θ_1 is equal to the angle β_1. In other embodiments, the angle θ_1 is not equal to the angle β_1. The half mirrors **115**, **135**, are oriented at an angle θ_2 relative to the outward facing surfaces **112**, **132**, respectively, and the half mirrors **125**, **145** are oriented at an angle θ_2 relative to the outward facing surfaces **122**, **142**, respectively. In embodiments, the angle θ_2 is equal to the angle β_2. In other embodiments, the angle θ_2 is not equal to the angle β_2. In embodiments, the angle θ_1 is equal to the angle θ_2 and the angle β_1 is equal to the angle β_2. For example, θ_1 and θ_2 can be generally equal to 45° (+/−1°), and β_1 and β_2 can be generally equal to 45° (+/−1°).

[0036] The four cloaking assembly components **110**, **120**, **130**, **140**, are transparent to incident light (both polarized and unpolarized) except for the half mirrors **115**, **125**, **135**, **145**, the outward facing mirror surfaces **118***a*, **128***a*, **138***a*, **148***a*, the inward facing opaque surfaces **118***b*, **128***b*, **138***b*, **148***b*, and optionally the outer end surfaces **116**, **126**, **136**, **146**. The four cloaking assembly components **110**, **120**, **130**, **140**, can be made from any suitable transparent material, for example a transparent glass or a transparent plastic. In the alternative, the four cloaking assembly components **110**, **120**, **130**, **140**, can be a structure, e.g. a frame, that holds the four CR boundary planes **118**, **128**, **138**, **148**, and the four half mirrors **115**, **125**, **135**, **145** in a desired orientation relative to each other with air or another gas present between the four CR boundary planes **118**, **128**, **138**, **148**, and the four half mirrors **115**, **125**, **135**, **145**. The frame may be a plurality of transparent glass or transparent plastic panes that hold the four CR boundary planes **118**, **128**, **138**, **148**, and the four half mirrors **115**, **125**, **135**, **145** in a desired orientation relative to each other with air or another gas present between the four CR boundary planes **118**, **128**, **138**, **148**, and the four half mirrors **115**, **125**, **135**, **145**. In embodiments, transparent glass or transparent plastic panes form the outward facing surfaces **112**, **122**, **132**, **142**, inward facing surfaces **114**, **124**, **134**, **144**, and outer end surfaces **116**, **126**, **136**, **146**, and hold the four CR boundary planes **118**, **128**, **138**, **148**, and the four half mirrors **115**, **125**, **135**, **145** in a desired orientation relative to each other with air or another gas present between the four CR boundary planes **118**, **128**, **138**, **148**, and the four half mirrors **115**, **125**, **135**, **145**.

[0037] The outer end surfaces **116**, **126**, **136**, **146**, may be transparent, have an absorber layer disposed thereon or be a half-mirror. In embodiments, the outer end surfaces **116**, **126**, **136**, **146**, are transparent. In other embodiments, the outer end surfaces **116**, **126**, **136**, **146**, have an absorber layer disposed thereon that absorbs incident light from within the four cloaking assembly components **110**, **120**, **130**, **140**, and/or from outside the four cloaking assembly components **110**, **120**, **130**, **140**. The absorber layer may be made from any suitable material that absorbs approximately 90% (+/−10%) of incident light, illustratively including dark colored surfaces made of glass, polymers, metals, ceramics, composites, etc. In other embodiments, the outer end surfaces **116**, **126**, **136**, **146**, are half-mirrors such that one mode of incident light is reflected (e.g., s-polarized light or p-polarized light) and another mode of incident light is transmitted through the half mirror (e.g., p-polarized light or s-polarized light, respectively). In other embodiments, one or more of the outer end surfaces **116**, **126**, **136**, **146**, is transparent and one or more of the outer end surfaces **116**, **126**, **136**, **146**, has an absorber layer disposed thereon. In other embodiments, one or more outer end surfaces **116**, **126**, **136**, **146**, is transparent and one or more of the outer end surfaces **116**, **126**, **136**, **146**, is a half mirror. In other embodiments, one or more of the outer end surfaces **116**, **126**, **136**, **146**, has an absorber layer disposed thereon and one or more of the outer end surfaces **116**, **126**, **136**, **146**, is a half mirror. In other embodiments, one or more of the outer end surfaces **116**, **126**, **136**, **146**, is transparent, one or more of the outer end surfaces **116**, **126**, **136**, **146**, has an absorber layer disposed thereon, and one or more of the outer end surfaces **116**, **126**, **136**, **146**, is a half mirror.

[0038] While FIGS. **1-2** illustrate four cloaking assembly components **110**, **120**, **130**, **140**, it should be appreciated that the four CR boundary planes **118**, **128**, **138**, **148**, and the four half mirrors **115**, **125**, **135**, **145** can be contained within any number of cloaking assembly components. For example, in embodiments, the cloaking assembly components **110** and **120** may be a single cloaking assembly component with no inward facing surface **114**, **124**, between the outward facing surfaces **112**, **122**, and the cloaking assembly components **130** and **140** may be a single cloaking assembly component with no inward facing surface **134**, **144**, between the outward facing surfaces **132**, **142**. In other embodiments, the cloaking assembly components **110** and **130** may be a single cloaking assembly component and the two cloaking assembly components **120** and **140** can be a single cloaking assembly component. In other embodiments, three of the four cloaking assembly components **110**, **120**, **130**, **140** may be a single cloaking assembly component assembled with a remaining one of the cloaking assembly components **110**, **120**, **130**, **140**. For example, the three cloaking assembly components **110**, **120**, **130** may be a single cloaking assembly component assembled with the remaining cloaking assembly component **140**. In other embodiments, the four cloaking assembly components **110**, **120**, **130**, **140** may be a single cloaking assembly component.

[0039] Still referring to FIGS. **1-2**, light 'lo' is reflected from an object 'O' (e.g., a target object) located on the object-side **102** of the cloaking device, travels in the −Y direction, and is incident on and transmitted through the outward facing surfaces **112**, **132**. The light lo reflected from the obscured portions of the object 'O' located directly behind the CR in the +Y direction is reflected by the outward facing mirror surfaces **118***a*, **138***a* in the +X and −X directions, respectively. The light lo reflected in the +X and −X directions is incident on the half mirrors **115**, **135** respectively. As illustrated in FIG. **1**, the half mirrors **115**, **135** are p-polarization half mirrors that reflect the s-mode (ls) of the light lo and allow the p-mode (lp) of the light lo to pass through. The s-polarized light ls reflected from the half mirrors **115**, **135** in the −Y direction is incident on the half mirrors **125**, **145**, respectively. The half mirrors **125**, **145** are also p-polarization mirrors that reflect the s-polarized light ls traveling in the −Y direction into the −X and +X directions, respectively. The s-polarized light ls reflected in in the −X and +X directions is incident on the outward facing mirror surfaces **128***a*, **148***a*, respectively, and the outward facing mirror surfaces **128***a*, **148***a* reflect the incident s-polarized light ls into the −Y direction. The s-polarized light reflected into the −Y direction by the outward facing mirror surfaces **128***a*, **148***a*, forms an image of the obscured portion of the target object located directly above the CR **200** in the +Y direction that is visible to an observer viewing the image-side **104** of the cloaking assembly **10**. In embodiments, the optical filter **125***b*, the optical filter **145***b*, or both optical filters **125***b*, **145***b* may be positioned on or adjacent to the outward facing surfaces **122**, **142**, respectively, as described above, and may convert the s-polarized light reflected into the −Y direction by the outward facing mirror surfaces **128***a*, **148***a*, into circularly polarized light or p-polarized light. For example, the optical filter **125***b* the optical filter **145***b*, or both optical filters **125***b*, **145***b* may be quarter wave plates that convert the s-polarized light reflected into the −Y direction by the outward facing mirror surfaces **128***a*, **148***a* into circularly polarized light (not shown) before forming the image of the obscured portion of the target object 'O' located directly above the CR **200** in the +Y direction. In the alternative, the optical filter **125***b*, the optical filter **145***b*, or both optical filters **125***b*, **145***b* may be a quarter-wave plate and a linear polarizer that converts the s-polarized light reflected into the −Y direction by the outward facing mirror surfaces **128***a*, **148***a* into circularly polarized light (not shown) and then converts the circularly polarized light into p-polarized light before forming the image of the obscured portion of the target object 'O' located directly above the CR **200** in the +Y direction.

[0040] Light lo reflected from the visible portions of the target object 'O' not located directly behind the CR in the +Y direction is incident on and transmitted through the outward facing surfaces **112**, **132**. The transmitted light lo is incident on the p-polarization half mirrors **115**, **135**. The half mirrors **115**, **135** reflect the s-mode is of the incident light lo in the +X and −X directions, respectively, and transmit the p-mode lp of the incident light lo in the −Y direction. The p-polarized light lp transmitted through the half mirrors **115**, **135** will be incident on and be transmitted through the p-polarization half mirrors **125**, **145**, respectively, in the –Y direction. The p-polarized light lp transmitted in the –Y direction by the half mirrors **125**, **145** forms an image of the visible portions of the target object O not located directly behind the CR **200** in the +Y direction that is visible to an observer viewing the cloaking assembly in the +Y direction. In embodiments, the optical filter **125***a*, the optical filter **145***a*, or both optical filters **125***a*, **145***a* may be positioned on or adjacent to the outward facing surfaces **122**, **142**, respectively, as described above, in order to convert the p-polarized light into circularly polarized light of s-polarized light. For example, the optical filter **125***a*, the optical filter **145***a* or both optical filters **125***a*, **145***a* may be quarter wave plates that convert the p-polarized light transmitted into the –Y direction by the half mirrors **125**, **145** into circularly polarized light (not shown) before forming the image of the visible portions of the target object 'O' not located behind above the CR **200** in the +Y direction. In the alternative, the optical filter **125***a*, the optical filter **145***a*, or both optical filters **125***a*, **145***a* may be a quarter-wave plate and a linear polarizer that convert the p-polarized light reflected into the –Y direction by the outward facing mirror surfaces **128***a*, **148***a* into circularly polarized light (not shown) and then convert the circularly polarized light into s-polarized light before forming the image of the visible portions of the target object 'O' not located directly above the CR **200** in the +Y direction. Accordingly, an image 'I' of the entire target object 'O' (both the obscured portion and the visible portions) is visible to the observer viewing the image-side **104** of the cloaking assembly **10**. While half mirrors **115**, **125**, **135**, **145** are described herein as p-polarization half mirrors, it should be appreciated that half mirrors **115**, **125**, **135**, **145** can be s-polarization half mirrors and the reflected and transmitted portions of the reflected light lo discussed above will be reversed. However, the human eye cannot distinguish between s-polarized light, p-polarized light or circularly polarized light and the image 'I' of the entire object 'O' will be visible to the human eye when an observer is viewing the image-side **104** of the cloaking assembly **10**. Also, it should be appreciated that the one or more of optical filters **125***a*, **125***b*, **145***a*, **145***b* may be positioned on or adjacent to outward facing surfaces **122**, **142** as described above such that only p-polarized light forms the image 'I', only s-polarized light forms the image 'I', only circularly polarized light forms the image 'I', only p-polarized light and circularly polarized light form the image 'I' or only s-polarized light and circularly polarized light form the image 'I'. Such manipulation of the polarized light reflected into the –Y direction by the outward facing mirror surfaces **128***a*, **128***a* and the polarized light transmitted in the –Y direction by the half mirrors **125**, **145** may assist an observer wearing polarized sunglasses in viewing the image-side **104** of the cloaking assembly **10**. Particularly, the one or more optical filters **125***a*, **125***b*, **145***a*, **145***b* ensure that polarized sunglasses that block p-polarized light or s-polarized light do not prevent an observer wearing such polarized sunglasses from seeing the entire target object 'O' when viewing the image-side **104** of the cloaking assembly **10**.

[0041] Referring now to FIGS. **1-4**, a top perspective view and a side view of a cloaking device according to embodiments (as discussed with respect to FIGS. **1-2**) are shown in FIGS. **3-4**, respectively. Specifically, FIG. **3** is a top perspective view of an article in the form of a column 'C' within the CR **200** of the cloaking assembly **10** and an automobile 'A' located behind the column C on the object-side **102** of the cloaking assembly **10** in the +Y direction. The column C has a height dimension in the Z direction (increasing height in the –Z direction) greater than the height h of the cloaking device. FIG. **4** is a side view from the +Y direction of the cloaking assembly **10** shown in FIG. **3** and shows the portion of the column C that is within the CR **200** is not visible and the automobile A located behind the column C in the +Y direction is visible to an observer viewing the cloaking assembly **10** in the +Y direction. Accordingly, the column C positioned within the CR **200** is not visible to an observer viewing the image-side **104** of the cloaking assembly **10** and an image of the entire automobile A (both the obscured portion and the visible portions) is visible to the observer viewing the image-side **104**. Although column C in FIGS. **3-4** is separate from the CR boundary planes **118**, **128**, **138**, **148**, i.e., column C is a separate object from the cloaking device **10**, it should be appreciated that column C may be structurally part of the cloaking device **10** and have an outer surface that provides or is equivalent to the CR boundary planes **118**, **128**, **138**, **148** with outward facing mirror surfaces **118***a*, **128***a*, **138***a*, **148***a*, respectively.

[0042] Referring now to FIGS. **1-5**, FIG. **5** shows embodiments of a cloaking assembly **12** with an enlarged CR **200**. Particularly, the cloaking assembly components **110**, **120**, **130**, **140** are arranged such that the cloaking assembly components **110**, **130** are spaced apart in the Y direction from the cloaking assembly components **120**, **140**, and a distance 'd' is between the inward facing surfaces **114**, **124**, and between the inward facing surfaces **134**, **144**. The area of the CR **200** in the X-Y plane is increased by the width 'w' times the distance d (w x d). The volume of the CR **200** is increased by the width w times the distance d times the height h (FIG. **4**) of the CR **200** (w x d x h). While FIG. **5** illustrates four cloaking assembly components **110**, **120**, **130**, **140**, it should be appreciated that the four CR boundary planes **118**, **128**, **138**, **148**, and the four half mirrors **115**, **125**, **135**, **145** can be contained within any number of cloaking assembly components. For example, in embodiments, the cloaking assembly components **110** and **130** may be a single cloaking assembly component and the two cloaking assembly components **120** and **140** can be a single cloaking assembly component.

[0043] As shown in the FIG. **5**, light lo is reflected from the target object O, travels in the –Y direction and is incident on and transmitted through the outward facing surfaces **112**, **132**. Light lo reflected from the obscured portions of the object located directly behind the CR in the +Y direction is reflected by the outward facing mirror surfaces **118***a*, **138***a* in the +X and –X direction, respectively. The reflected light lo in the +X and –X directions is incident on the half mirrors **115**, **135** respectively. The half mirrors **115**, **135** are p-polarization half mirrors and reflect the s-mode is of the light lo and transmit the p-mode lp of the light lo. The s-polarized light ls reflected by the half mirrors **115**, **135** in the –Y direction is incident on the half mirrors **125**, **145**, respectively. The half mirrors **125**, **145** are also p-polarization mirrors that reflect the s-polarized light ls traveling in the –Y direction into the –X and +X directions, respectively. The s-polarized light ls traveling in the –X and +X directions is incident on the outward facing mirror surfaces **128***a*, **148***a*, respectively, and the outward facing mirror surfaces **128***a*, **148***a* reflect the incident s-polarized light ls in the –Y direction. The s-polarized light reflected in the –Y direction by the outward facing mirror surfaces **128***a*, **148***a*, forms an image of the obscured portion of the object located behind the CR **200** in the +Y direction that is visible to an observer viewing the image-side **104** of the cloaking assembly **12**. Light lo reflected from the visible portions of the target object O not located behind the CR **200** in the +Y direction is incident on and transmitted through the outward facing surfaces **112**, **132**. The transmitted light lo is incident on the p-polarization half mirrors **115**, **135**, and the half mirrors **115**, **135** reflect the s-mode is of the incident light lo in the +X and −X directions, respectively, and transmit the p-mode lp of the incident light lo in the −Y direction. The p-polarized light lp transmitted through the half mirrors **115**, **135** in the −Y direction is incident on and transmitted through the p-polarization half mirrors **125**, **145**, respectively, in the −Y direction. The p-polarized light lp transmitted in the −Y direction through the half mirrors **125**, **145**, forms an image of the visible portions of the target object O not located behind the CR **200** in the +Y direction that is visible to an observer viewing the image side **104** of the cloaking assembly **12**. Accordingly, an image I of the entire target object O (both the obscured portion and the visible portions) is visible to an observer viewing the image-side **104** of the cloaking assembly **12**. It should be appreciated that half mirrors **115**, **125**, **135**, **145**, can be s-polarization half mirrors and the reflected and transmitted portions of the reflected light lo discussed above will be reversed. Also, it should be appreciated that the one or more of optical filters **125***a*, **125***b*, **145***a*, **145***b* may be included. However, the human eye cannot distinguish between s-polarized light, p-polarized light or circularly polarized light and the image I of the entire object O will be visible to an observer viewing the image-side **104** of the cloaking assembly **12**.

[0044] Referring now to FIGS. **1-7**, a top perspective view and a side view of a cloaking device according to embodiments (as discussed with respect to FIG. **5**) are shown in FIGS. **6-7**, respectively. Specifically, FIG. **6** is a top perspective view of a first article in the form of a column '**C1**' and a second article in the form of a column '**C2**' within the CR **200** of the cloaking assembly **12** and the automobile 'A' located behind the columns C**1**, C**2** on the object-side **102** of the cloaking assembly **12** in the +Y direction. The column C**1** has a first height dimension in the Z direction and the column C**2** has a second height dimension that is greater (in the −Z direction) than the first height dimension of column C**1**. The first height dimension of column C**1** and the second height dimension of column C**2** are both greater than the height h of the cloaking assembly **12**. FIG. **7** is a side view from the +Y direction of the cloaking assembly **12** shown in FIG. **6** and shows the image-side **104**. Portions of column C**1** and column C**2** within the CR **200** are not visible and automobile A located behind column C**1** and column C**2** in the +Y direction is visible to an observer viewing the image-side **104** of the cloaking assembly **12**. Although columns C**1**, C**2** in FIGS. **6-7** are separate from the CR boundary planes **118**, **128**, **138**, **148**, i.e., columns C**1**, C**2** are separate objects from the cloaking device **12**, it should be appreciated that columns C**1**, C**2** may be structurally part of the cloaking device **12** and have an outer surface that provides or is equivalent to the CR boundary planes **118**, **128**, **138**, **148** with outward facing mirror surfaces **118***a*, **128***a*, **138***a*, **148***a*, respectively.

[0045] Referring to FIG. **8**, embodiments of a cloaking device that can display additional images in conjunction with the images depicted in FIGS. **1**, **4**, **5** and **7** are shown. Particularly, FIG. **8** shows an item in the form of the number '1' (item 1) and an item in the form of the number '2' (item 2) located adjacent to the outer end surfaces **126**, **146**, respectively, in the +X, −X directions, respectively. Light lo reflected from item 1 and item 2 is incident on and transmitted through the outer end surfaces **126**, **146** in the −X, +X directions, respectively. The light lo transmitted through the outer end surfaces **126**, **146** is incident on the half mirrors **125**, **145**, respectively. The half mirrors **125**, **145** (p-polarization half mirrors) transmit the p-mode lp of the light lo in the −X, +X directions, respectively, and reflect the s-mode is of the light lo into the −Y direction. The transmitted p-polarized light lp in the −X, +X directions is incident on the outward facing mirror surfaces **128***a*, **148***a*, respectively. The outward facing mirror surfaces **128***a*, **148***a*, reflect the incident p-polarized light lp into the −Y direction. The s-polarized light ls reflected by the half mirror **125** in the −Y direction forms a reversed '1' image on the right hand side of the outward facing surface **122** and the s-polarized light ls reflected by the half mirror **145** in the −Y direction forms a reversed '2' image on the left hand side of the outer facing surface **142**. The p-polarized light lp reflected by the outward facing mirror surface **128***a* into the −Y direction forms a reversed '1' image on the left hand side of the outward facing surface **122** and the p-polarized light lp reflected by the outward facing mirror surface **148***a* into the −Y direction forms a reversed '2' image on the right hand side of the outer facing surface **142**. It should be appreciated that the display of additional images as depicted in FIG. **8** in conjunction with images as depicted in FIGS. **1**, **4**, **5** and **7** can be used as part of a heads-up display, a warning system (signal) that an object is located on the object side of the cloaking device, etc.

[0046] Referring to FIGS. **1-10**, embodiments of a cloaking device with a cloaking assembly **14** having items in the form of '1', '2', '3', '4' adjacent to the outer end surfaces **126**, **146**, **116**, **136**, respectively are shown in FIG. **9**. FIG. **10** is a side view of the cloaking assembly **14** illustrated in FIG. **9** with reversed images of item 1 and item 2, in conjunction with the image of the automobile A, visible on the image-side **104** of the cloaking assembly **14**. It should be appreciated that items 1, 2, 3, 4 depicted in FIGS. **9-10** are shown for illustrative purposes only, i.e. the items 1, 2 in FIG. **9** could be oriented in the Y-Z plane in order to provide reverse images of items 1, 2 on the image side **104** (X-Z plane) in FIG. **10**. It should also be appreciated that reverse images of item 3 and item 4 can be formed or provided on the object-side **102** of the cloaking assembly **14** in a similar manner as the reversed images of item 1 and item 2 are formed on the image-side **104**.

[0047] Referring to FIGS. **1-8** and **11**, embodiments of a cloaking device that can selectively display images in conjunction with the images depicted in FIGS. **1**, **4**, **5** and **7** are shown. Particularly, FIG. **11** shows an item in the form of the number '1' and an item in the form of the number '2' located adjacent to the outer end surfaces **126**, **146**, respectively, in the +X, −X directions, respectively. Light lo from item 1 is incident on an s-polarizer **150**. The s-polarizer **150** allows the s-mode is of the incident light lo to pass through in the −X direction. The s-polarized light ls is incident on and reflected by the p-polarization half mirror **125** into the Y direction and no light is transmitted through or beyond the p-polarization half mirror **125** in the −X direction. Accordingly, a reversed image of item 1 is formed only on the right hand side of the outward facing surface **122**. The light lo from item 2 is transmitted through the outer end surface **146** in the +X direction and is incident on the p-polarization half mirror **145**. The p-polarization half mirror **145** transmits the p-mode lp of the incident light lo in the +X direction and reflects the s-mode is of the incident light lo in the −Y direction. The p-polarized light lp in the +X direction is incident on the outward facing mirror surface **148***a*. The outer facing mirror surface **148***a* reflects the incident p-polarized light lp in the −Y direction. The s-polarized light ls reflected by the half mirror **145** in the −Y direction forms a reversed item 2 image on the left hand side of the outer facing surface **142**. The p-polarized light lp reflected by the outer facing mirror surface **148***a* into the −Y direction provides a reversed item 2 image on the right hand side of the outer facing surface **142**.

[0048] Referring to FIGS. **1-8** and **11-13**, embodiments of a cloaking device with a cloaking assembly **16** having items in the form of '1' and '2' adjacent to the outer end surfaces **126**, **146**, respectively, and the s-polarizer **150** adjacent the outer end surface **126**, are shown in FIG. **12**. FIG. **13** is a side view of the cloaking assembly **16** illustrated in FIG. **12** with the reversed image of item 1 visible on the right hand side of the outer facing surface **122** of the cloaking assembly component **120** and the reversed image of item 2 visible on the left hand side and right hand side of the outward facing surface **142** of the cloaking assembly components **140** shown in conjunction with the image of the automobile A. It should be appreciated that items 1, 2 depicted in FIG. **12** are shown for illustrative purposes only, i.e. the items 1, 2 in FIG. **12** could be oriented in the Y-Z plane in order to provide the reverse images of items 1, 2 on the image-side (**104**) (X-Z plane) shown in FIG. **13**.

[0049] Referring to FIGS. **1-8** and **14**, another embodiment of a cloaking device that can selectively display additional images in conjunction with the images depicted in FIGS. **1**, **4**, **5** and **7** is shown. Particularly, FIG. **14** shows an item in the form of the number '1' and an item in the form of the number '2' located adjacent to the outer end surfaces **126**, **146**, respectively, in the +X, −X directions, respectively. Light lo reflected from the item 1 is incident on a p-polarizer **152** which allows p-polarized light lp to pass through in the −X direction. The p-polarized light lp is incident on the p-polarization half mirror **125**. The incident p-polarized light lp in the −X direction is transmitted through the p-polarization half mirror **125** in the −X direction and there is no s-polarized light is to be reflected by the p-polarization half mirror **125** in the −Y direction. The p-polarized light lp transmitted through the p-polarization half mirror **125** is incident on the outward facing mirror surface **128***a* and the outward facing mirror **128***a* reflects the p-polarized light lp into the −Y direction. Accordingly, a reversed image of item 1 is formed only on the left hand side of the outward facing surface **122**. The light lo reflected from item 2 is transmitted through the outer end surface **146** in the +X direction and is incident on the p-polarization half mirror **145**. The p-polarization half mirror **145** transmits the p-mode lp of the incident light lo in the +X directions and reflects the s-mode ls of the incident light lo into the −Y direction. The p-polarized light lp in the +X is incident on the outer facing mirror surface **148***a*. The outer facing mirror surface **148***a* reflects the incident p-polarized light lp into the −Y direction. The s-polarized light ls reflected by the half mirror **145** in the −Y direction forms a reversed 2 on the left hand side of the outer facing surface **142** and the p-polarized light lp reflected by the outer facing mirror surface **148***a* in the −Y direction forms a reversed 2 image on the right hand side of the outer facing surface **142**.

[0050] Referring to FIGS. **1-8** and **14-16**, embodiments of a cloaking device with a cloaking assembly **18** having items 1 and items 2 adjacent to the outer end surfaces **126**, **146**, respectively, and the p-polarizer **152** adjacent to the outer end surface **126**, are shown in FIG. **15**. FIG. **16** is a side view of the cloaking assembly **18** illustrated in FIG. **15** with the single reversed image of item 1 visible on the left hand side of the outer facing surface **122** of the cloaking assembly component **120** and the reversed image of item 2 visible on the left hand side and right hand side of the outward facing surface **142** of the cloaking assembly components **140** in conjunction with the image of the automobile A. It should be appreciated that items 1, 2 depicted in FIG. **15** are shown for illustrative purposes only, i.e. the items 1, 2 in FIG. **15** could be oriented in the Y-Z plane in order to provide the reverse images of items 1, 2 on the image-side **104** (X-Z plane) shown in FIG. **16**.

[0051] Referring to FIGS. **1**, **2**, **5**, **8-17**, embodiments of an A-pillar of a vehicle being cloaked by a cloaking device are shown. Particularly, FIG. **17** shows a cloaking device **19** cloaking a portion of an A-pillar P of a vehicle V. A portion of the A-pillar P is positioned within a CR **200** (not shown) of the cloaking device **19** and a portion of the A-pillar P extends beyond the cloaking device and is covered with trim T. Illustrated outside of the vehicle V is a target object O in the form of pedestrian. A portion of the pedestrian O is visible through a side window of the vehicle V and a portion of the pedestrian is visible "through" the A-pillar P cloaked by the cloaking device **19**. The cloaking device **19** redirects light reflected from the pedestrian O around the A-pillar P positioned within the CR **200** of the cloaking device **19** and forms an image I of the pedestrian O on an image-side **104** of the cloaking device **19** that is visible to an occupant of the vehicle V looking towards the pedestrian O. Accordingly, light from the pedestrian O appears to pass through the A-pillar P and a blind spot typically created by the A-pillar P is not present. In embodiments, the A-pillar P itself serves as the CR **200**, i.e. the A-pillar P has an outer surface with one or more outer facing mirror surfaces that assist in redirecting light from the pedestrian) around the A-pillar P. It should be appreciated that cloaking of the A-pillar P with the cloaking device **19** and removing the blind spot produced by the A-pillar P is performed without the use of metamaterials, video images, cameras, sophisticated electronics, etc.

[0052] Referring to FIGS. **18-19**, alternative embodiments of cloaking devices are shown. Specifically, FIG. **18** shows a cloaking device **20** with a circular CR **202** having an outer mirror surface **204** with half mirrors **206**, **208** around the outer mirror surface **204** having a circular shape. In embodiments, the CR **202** is provided by an object to be cloaked itself, e.g., an A-pillar, B-pillar, C-pillar, D-pillar, etc., that has an out outer mirror surface **204**. The cloaking device shown in FIG. **18** can increase the field of view for an observer viewing the cloaking device **20** in the +Y direction. FIG. **19** shows a cloaking device **30** with a circular CR **302** having an outer mirror surface **304** with half mirrors **306**, **308** and optical components **310**, **312** such as lenses. In embodiments, the CR **302** is provided by an object to be cloaked itself, e.g., an A-pillar, B-pillar, C-pillar, D-pillar, etc., that has an out outer mirror surface **304**. The cloaking device shown in FIG. **19** allows for an external view from an object located behind the CR **302** (+Y direction) to be manipulated to increase a field of view or to normalize a distorted image.

[0053] The cloaking devices described herein may be used to cloak vehicle articles such as a vehicle A-pillar, B-pillar, C-pillar, D-pillar, etc., and remove a "blind spot" caused by the vehicle article. It will be understood that the term "blind spot" as used herein refers to an area around the vehicle that cannot be directly observed by a driver while operating the vehicle. The terms "object," "article," and "item" may interchangeably refer to a visual object or image (2D or 3D) that reflects light or transmits light and the team "light from" may refer to "light reflected from" or "light transmitted from." The terms "generally," "approximately," and "about" may be utilized herein to represent the inherent degree of uncertainty that may be attributed to any quantitative comparison, value, measurement, or other representation. These terms are also utilized herein to represent the degree by which a quantitative representation may vary from a stated reference without resulting in a change in the basic function of the subject matter at issue.

[0054] While particular embodiments have been illustrated and described herein, it should be understood that various other changes and modifications may be made without departing from the spirit and scope of the claimed subject matter. Moreover, although various aspects of the claimed subject matter have been described herein, such aspects need not be utilized in combination. It is therefore intended that the appended claims cover all such changes and modifications that are within the scope of the claimed subject matter.

What is claimed is:

1. A cloaking device comprising:
- an object-side and an image-side;
- a cloaking region (CR) boundary plane having an outward facing mirror surface and an inward facing opaque surface;
- a CR at least partially bounded by the inward facing opaque surface of the CR boundary plane;
- a half mirror spaced apart and generally parallel to the outward facing mirror surface;
- wherein light from an object located on the object-side of the cloaking device and obscured by the CR is redirected around the CR to form an image of the object on the image-side of the cloaking device such that the light from the object appears to pass through the CR.

2. The cloaking device of claim **1**, wherein the half mirror is selected from a p-polarization half mirror and an s-polarization half mirror.

3. The cloaking device of claim **1**, further comprising an article positioned within the CR, wherein the light from the object located on the object-side of the cloaking device and obscured by the CR is redirected around the CR and the article to form the image of the object on the image-side of the cloaking device such that the article appears transparent.

4. The cloaking device of claim **3**, wherein the article is selected from the group consisting of a vehicle A-pillar, a vehicle B-pillar and a vehicle C-pillar.

5. The cloaking device of claim **1**, further comprising:
- at least two CR boundary planes positioned non-planar to each other, each of the at least two CR boundary planes having an outward facing mirror surface and an inward facing opaque surface, the CR at least partially bounded by the inward facing opaque surfaces of the at least two CR boundary planes;
- at least one quarter-wave plate positioned on or adjacent to the image side; and
- at least two half mirrors spaced apart and generally parallel to the outward facing mirror surfaces such that a half mirror is spaced apart and generally parallel to each outward facing mirror surface;
- wherein the light from the object located on the object-side of the cloaking device and obscured by the CR is redirected around the CR by the at least two outward facing mirror surfaces and the at least two half mirrors, and the image of the object is formed on the image-side of the cloaking device such that the light from the object located on the object-side of the cloaking device appears to pass through the CR.

6. The cloaking device of claim **5**, wherein the at least two CR boundary planes are positioned orthogonal to each other.

7. The cloaking device of claim **6**, wherein the light from the object on the object-side of the cloaking device is reflected by a first outward facing mirror surface, a first half mirror positioned parallel to the first outward facing mirror surface, a second half mirror positioned orthogonal to the first half mirror, a second outward facing mirror surface positioned parallel to the second half mirror, and transmitted through the at least one quarter-wave plate before forming the image of the object on the image-side of the cloaking device.

8. The cloaking device of claim **7**, further comprising a vehicle article positioned within the CR, wherein the light from the object located on the object-side of the cloaking device and obscured by the CR is redirected around the CR and the vehicle article to form the image of the object on the image-side of the cloaking device and the vehicle article appears transparent.

9. The cloaking device of claim **5**, further comprising an end side, wherein light from an item positioned adjacent to the end side forms an image of the item on the image-side of the cloaking device.

10. A cloaking device for cloaking an article of a vehicle comprising:
- a cloaking assembly comprising:
  - an object-side and an image-side;
  - at least two CR boundary planes located at least partially between the object-side and the image-side, the at least two CR boundary planes positioned non-planar to each other and each of the at least two CR boundary planes having an outward facing mirror surface and an inward facing opaque surface;
  - a CR bounded by the inward facing opaque surfaces of the at least two CR boundary planes;
  - at least two half mirrors located at least partially between the object-side and the image-side, each of the at least two half mirrors spaced apart and generally parallel to one of the outward facing mirror surfaces such that a half mirror is spaced apart and generally parallel to each outward facing mirror surface;
  - at least one quarter-wave plate positioned on or adjacent to the image side;
  - and
  - a vehicle article positioned within the CR;

wherein light from an object located on the object-side of the cloaking assembly and obscured by the CR is redirected around the CR and forms an image of the object on the image-side of the cloaking assembly such that the vehicle article appears to be transparent.

11. The cloaking device of claim **10**, wherein the vehicle article is selected from the group consisting of a vehicle A-pillar, a vehicle B-pillar and a vehicle C-pillar.

12. The cloaking device of claim **10**, wherein the light from the object is reflected by a first outward facing mirror surface, a first half mirror oriented generally parallel to the first outward facing mirror surface, a second half mirror oriented generally orthogonal to the first half mirror and a second outward facing mirror surface oriented generally parallel to the second half mirror and transmitted through the at least one quarter-wave plate before forming the image on the image-side of the cloaking assembly.

13. The cloaking device of claim **12**, further comprising an end surface, wherein light from an item located adjacent to the end surface passes through the cloaking assembly and forms an image of the item on the image-side of the cloaking assembly.

14. The cloaking device of claim **13**, wherein a p-mode or an s-mode of the light from the item is reflected from the second half mirror before forming the image of the item on the image-side of the cloaking assembly.

15. The cloaking device of claim **13**, wherein a p-mode or an s-mode of the light from the item is transmitted through the second half mirror and reflected by the second outward facing mirror surface before forming the image of the item on the image-side of the cloaking assembly.

16. A cloaking device comprising:

four CR boundary planes positioned non-planar to each other, each of the four CR boundary planes having an outward facing mirror surface and an inward facing opaque surface;

a CR bounded by the inward facing opaque surfaces of the four CR boundary planes;

an article located at least partially within the CR;

four half mirrors spaced apart and generally parallel to the outward facing mirror surfaces such that a half mirror is spaced apart and generally parallel to each outward facing mirror surface;

wherein light from an object on an object-side of the cloaking device is redirected around the CR and appears as an image on an image-side of the cloaking device and is visible to an observer viewing the image-side of the cloaking device and the article within the CR is not visible to the observer viewing the image-side of the cloaking device such that the article within the CR appears transparent to the observer viewing the image-side of the cloaking device.

17. The cloaking device of claim **16**, wherein the light from the object is reflected by a first outward facing mirror surface, a first half mirror oriented generally parallel to the first outward facing mirror surface, a second half mirror oriented generally orthogonal to the first half mirror and a second outward facing mirror surface oriented generally parallel to the second half mirror before forming the image on the image-side of the cloaking device.

18. The cloaking device of claim **17**, wherein the article is selected from at least one of a vehicle A-pillar, a vehicle B-pillar and a vehicle C-pillar.

19. The cloaking device of claim **18**, further comprising an end side, wherein light from an item located adjacent to the end side is reflected by at least one of the second half mirror and the second outward facing mirror surface and forms an image of the item on the image-side of the cloaking device.

20. The cloaking device of claim **19**, wherein the image of the item is selectively formed on the image-side of the cloaking device.

Preface

How to Have Fun with This Book

Everyone uses electronic devices, but most of us don't really know what goes on inside them.

Of course, you may feel that you don't need to know. If you can drive a car without understanding the workings of an internal combustion engine, presumably you can use an iPod without knowing anything about integrated circuits. However, understanding some basics about electricity and electronics can be worthwhile for three reasons:

- By learning how technology works, you become better able to control your world instead of being controlled by it. When you run into problems, you can solve them instead of feeling frustrated by them.
- Learning about electronics can be fun—so long as you approach the process in the right way. The tools are relatively cheap, you can do all the work on a tabletop, and it doesn't consume a lot of time (unless you want it to).
- Knowledge of electronics can enhance your value as an employee or perhaps even lead to a whole new career.

Learning by Discovery

Most introductory guides begin with definitions and facts, and gradually get to the point where you can follow instructions to build a simple circuit.

This book works the other way around. I want you to start putting components together right away. After you see what happens, you'll figure out what's going on. I believe this process of *learning by discovery* creates a more powerful and lasting experience.

Stay Within the Limits!

Although I believe that everything suggested in this book is safe, I'm assuming that you will stay within the limits that I suggest. Please always follow the instructions and pay attention to the warnings, denoted by the icon you see here. If you go beyond the limits, you will expose yourself to unnecessary risks.

Learning by discovery occurs in serious research, when scientists notice an unusual phenomenon that cannot be explained by current theory, and they start to investigate it in an effort to explain it. This may ultimately lead to a better understanding of the world.

We're going to be doing the same thing, although obviously on a much less ambitious level.

Along the way, you will make some mistakes. This is good. Mistakes are the best of all learning processes. I want you to burn things out and mess things up, because this is how you learn the limits of components and materials. Since we'll be using low voltages, there'll be no chance of electrocution, and so long as you limit the flow of current in the ways I'll describe, there will be no risk of burning your fingers or starting fires.

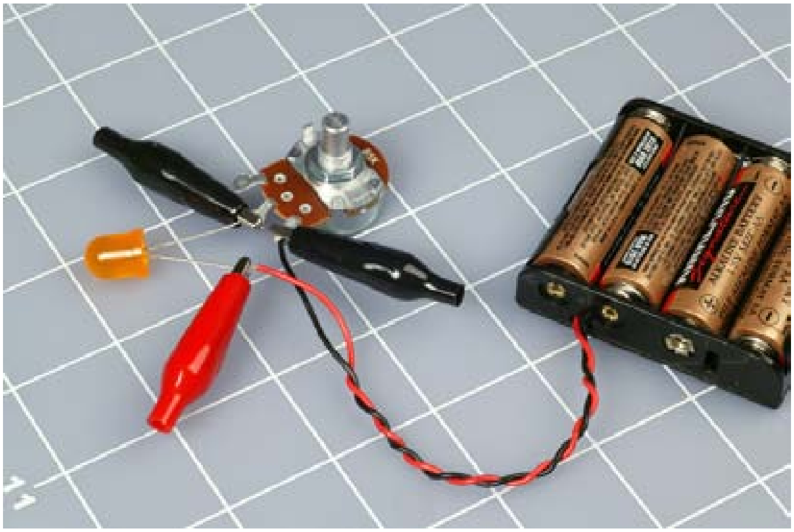

Figure P-1. *Learning by discovery allows you to start building simple circuits right away, using a handful of cheap components, a few batteries, and some alligator clips.*

How Hard Will It Be?

I assume that you're beginning with no prior knowledge of electronics. So, the first few experiments will be ultra-simple, and you won't even use solder or prototyping boards to build a circuit. You'll be holding wires together with alligator clips.

Very quickly, though, you'll be experimenting with transistors, and by the end of Chapter 2, you will have a working circuit that has useful applications.

I don't believe that hobby electronics has to be difficult to understand. Of course, if you want to study electronics more formally and do your own circuit design, this can be challenging. But in this book, the tools and supplies will be inexpensive, the objectives will be clearly defined, and the only math you'll need will be addition, subtraction, multiplication, division, and the ability to move decimal points from one position to another.

Moving Through This Book

Basically there are two ways to present information in a book of this kind: in tutorials and in reference sections. I'm going to use both of these methods. You'll find the tutorials in sections headed as follows:

- Shopping Lists
- Using Tools
- Experiments

You'll find reference sections under the following headings:

- Fundamentals
- Theory
- Background

How you use the sections is up to you. You can skip many of the reference sections and come back to them later. But if you skip many of the tutorials, this book won't be of much use to you. Learning by discovery means that you absolutely, positively have to do some hands-on work, and this in turn means that you have to buy some basic components and play with them. You will gain very little by merely imagining that you are doing this.

It's easy and inexpensive to buy what you need. In almost any urban or suburban area in the United States, chances are you live near a store that sells electronic components and some basic tools to work with them. I am referring, of course, to RadioShack franchises. Some Shacks have more components than others, but almost all of them have the basics that you'll need.

You can also visit auto supply stores such as AutoZone and Pep Boys for basics such as hookup wire, fuses, and switches, while stores such as Ace Hardware, Home Depot, and Lowe's will sell you tools.

If you prefer to buy via mail order, you can easily find everything you need by searching online. In each section of the book, I'll include the URLs of the most popular supply sources, and you'll find a complete list of URLs in the appendix.

Fundamentals

Mail-ordering components and tools

Here are the primary mail-order sources that I use myself online:

http://www.radioshack.com

RadioShack, a.k.a. The Shack. For tools and components. Not always the cheapest, but the site is easy and convenient, and some of the tools are exactly what you need.

http://www.mouser.com

Mouser Electronics.

http://www.digikey.com

Digi-Key Corporation.

http://www.newark.com

Newark.

Mouser, Digi-Key, and Newark are all good sources for components, usually requiring no minimum quantities.

http://www.allelectronics.com

All Electronics Corporation. A narrower range of components, but specifically aimed at the hobbyist, with kits available.

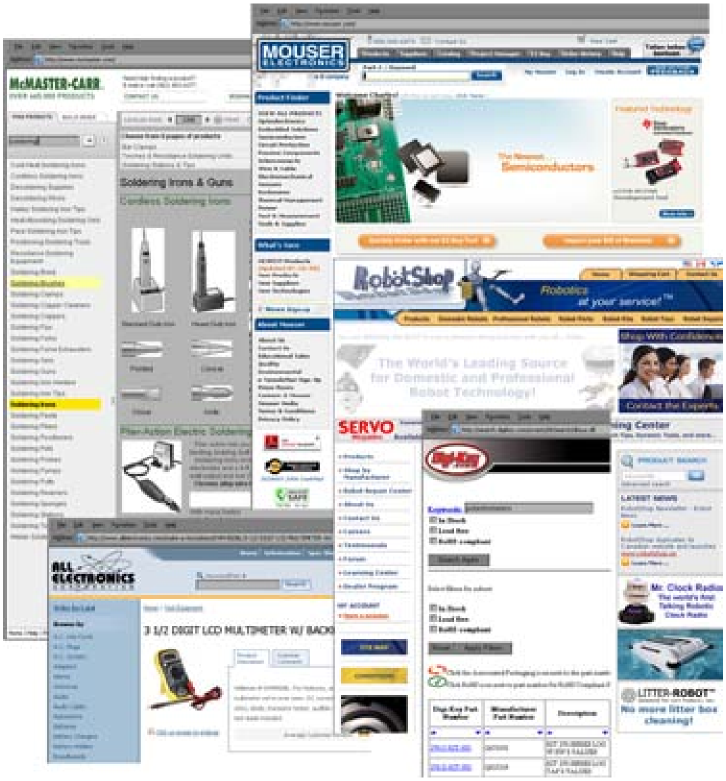
http://www.ebay.com

You can find surplus parts and bargains here, but you may have to try several eBay Stores to get what you want. Those based in Hong Kong are often very cheap, and I've found that they are reliable.

http://www.mcmaster.com

McMaster-Carr. Especially useful for high-quality tools.

Lowe's and Home Depot also allow you to shop online.



McMASTER-CARR
MOUSER ELECTRONICS
Soldering Irons & Guns
Cordless Soldering Irons
RobotShop
Robotics at your service!
The World's Leading Source for Domestic and Professional Robot Technology!
SERVO
Digi-Key
ALL ELECTRONICS
3 1/2 DIGIT LCD MULTIMETER W/ BACK
LITTER-ROBOT
Mr. Clock Radio

Figure P-2. *You'll find no shortage of parts, tools, kits, and gadgets online.*

Companion Kits

Maker Shed (*www.makershed.com*) offers a number of *Make: Electronics* companion kits, both toolkits and bundles of the various components used in the book's experiments. This is a simple, convenient, and cost-effective way of getting all the tools and materials you need to do the projects in this book.

Comments and Questions

Please address comments and questions concerning this book to the publisher:

O'Reilly Media, Inc.

Safari® Books Online

Safari Books Online is an on-demand digital library that lets you easily search over 7,500 technology and creative reference books and videos to find the answers you need quickly.

With a subscription, you can read any page and watch any video from our library online. Read books on your cell phone and mobile devices. Access new titles before they are available for print, and get exclusive access to manuscripts in development and post feedback for the authors. Copy and paste code samples, organize your favorites, download chapters, bookmark key sections, create notes, print out pages, and benefit from tons of other time-saving features.

O'Reilly Media has uploaded this book to the Safari Books Online service. To have full digital access to this book and others on similar topics from O'Reilly and other publishers, sign up for free at *http://my.safaribooksonline.com*.

Experiencing Electricity

1

I want you to get a taste for electricity—literally!—in the first experiment. This first chapter of the book will show you:

- How to understand and measure electricity and resistance
- How to handle and connect components without overloading, damaging, or destroying them

Even if you have some prior knowledge of electronics, you should try these experiments before you venture on to the rest of the book.

IN THIS CHAPTER

Shopping List: Experiments 1 Through 5
Experiment 1: Taste the Power!
Experiment 2: Let's Abuse a Battery!
Experiment 3: Your First Circuit
Experiment 4: Varying the Voltage
Experiment 5: Let's Make a Battery

Maker Shed (www.makershed.com) *has put together a series of* Make: Electronics *companion kits. These include all of the tools and components used in book's experiments. This is a quick, simple, and cost-effective way of getting everything you need to complete the projects in this book.*

Shopping List: Experiments 1 Through 5

If you want to limit your number of shopping trips or online purchases, look ahead in the book for additional shopping lists, and combine them to make one bulk purchase.

In this first chapter, I will give you part numbers and sources for every tool and component that we'll be using. Subsequently, I won't expect you to need such specific information, because you will have gained experience searching for items on your own.

Tools

Small pliers

RadioShack Kronus 4.5-inch, part number 64-2953 or Xcelite 4-inch mini long-nose pliers, model L4G.

Or similar. See Figures 1-1 through 1-3. Look for these tools in hardware stores and the sources listed in the preface. The brand is unimportant. After you use them for a while, you'll develop your own preferences. In particular, you have to decide whether you like spring-loaded handles. If you decide you don't, you'll need a second pair of pliers to pull the springs out of the first.

Wire cutters

RadioShack Kronus 4.5-inch, part number 64-2951, or Stanley 7-inch model 84-108.

Or similar. Use them for cutting copper wire, not harder metals (Figure 1-4).

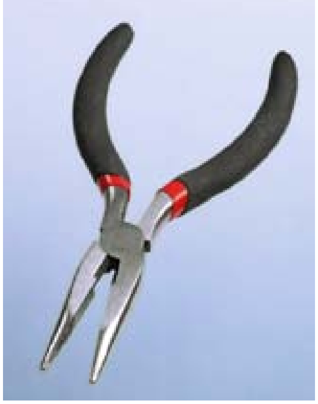

Figure 1-1. *Generic long-nosed pliers are your most fundamental tool for gripping, bending, and picking things up after you drop them.*

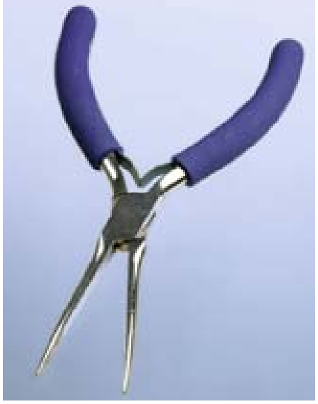

Figure 1-2. *Longer-nosed pliers: these are useful for reaching into tiny spaces.*

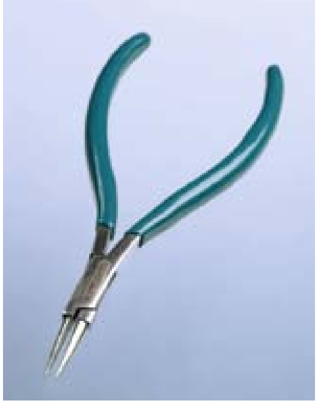

Figure 1-3. *Sharp-pointed pliers are designed for making jewelry, but are also useful for grabbing tiny components.*

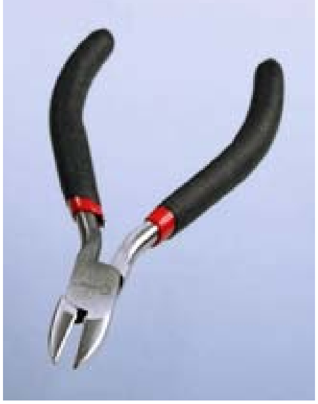

Figure 1-4. *Wire cutters, sometimes known as side cutters, are essential.*

Multimeter

Extech model EX410 or BK Precision model 2704-B or Amprobe model 5XP-A.

Or similar. Because electricity is invisible, we need a tool to visualize the pressure and flow, and a meter is the only way. A cheap meter will be sufficient for your initial experiments. If you buy online, try to check customer reviews, because reliability may be a problem for cheap meters. You can shop around for retailers offering the best price. Don't forget to search on eBay.

The meter must be digital—don't get the old-fashioned analog kind with a needle that moves across a set of printed scales. This book assumes that you are looking at a digital display.

I suggest that you do not buy an autoranging meter. "Autoranging" sounds useful—for example, when you want to check a 9-volt battery, the meter figures out for itself that you are not trying to measure hundreds of volts, nor fractions of a volt. The trouble is that this can trick you into making errors. What if the battery is almost dead? Then you may be measuring a fraction of a volt without realizing it. The only indication will be an easily overlooked "m" for "millivolts" beside the large numerals of the meter display.

On a manual-ranging meter, you select the range, and if the source that you are measuring is outside of that range, the meter tells you that you made an error. I prefer this. I also get impatient with the time it takes for the autoranging feature to figure out the appropriate range each time I make a measurement. But it's a matter of personal preference. See Figures 1-5 through 1-7 for some examples of multimeters.

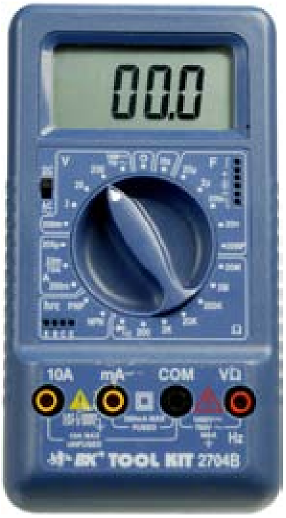

Figure 1-5. *You can see by the wear and tear that this is my own favorite meter. It has all the necessary basic features and can also measure capacitance (the F section, for Farads). It can also check transistors. You have to choose the ranges manually.*

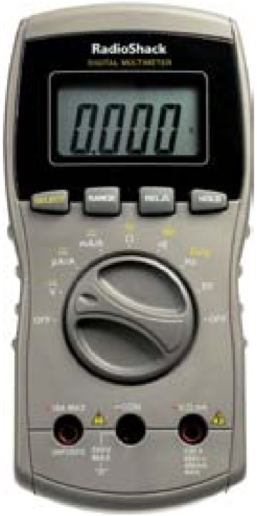

Figure 1-6. *Mid-priced RadioShack meter, which has the basic features; however, the dual purpose for each dial position, selected with the SELECT button, may be confusing. This is an autoranging meter.*

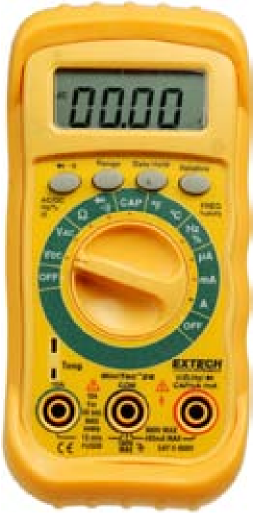

Figure 1-7. *An autoranging meter from Extech offers basic functions, plus a temperature probe, which may be useful to check whether components such as power supplies are running unduly hot.*

Supplies

Batteries

9-volt battery. Quantity: 1.

AA batteries, 1.5 volts each. Quantity: 6.

The batteries should be disposable alkaline, the cheapest available, because we may destroy some of them. You should *absolutely not* use rechargeable batteries in Experiments 1 and 2.

Battery holders and connectors

Snap connector for 9-volt battery, with wires attached (Figure 1-8). Quantity: 1. RadioShack part number 270-325 or similar. Any snap connector that has wires attached will do.

Battery holder for single AA cell, with wires attached (Figure 1-9). Quantity: 1. RadioShack part number 270-401 or Mouser.com catalog number 12BH410-GR, or similar; any single-battery holder that has thin wires attached will do.

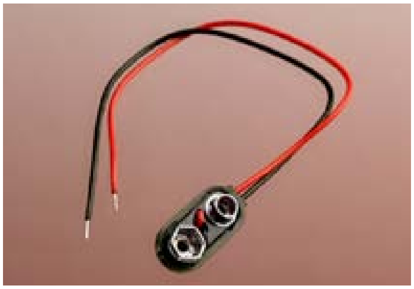

Figure 1-8. *Snap connector for a 9-volt battery.*

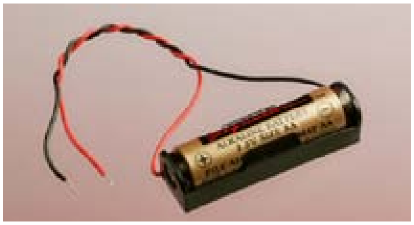

Figure 1-9. *Single AA-sized battery carrier with wires.*

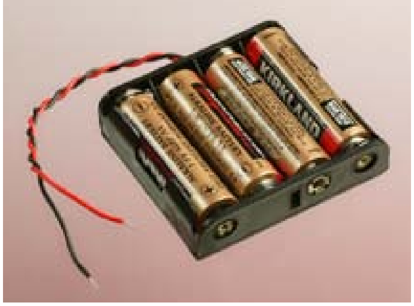

Figure 1-10. *Battery carrier for four AA cells, to be installed in series, delivering 6 volts.*

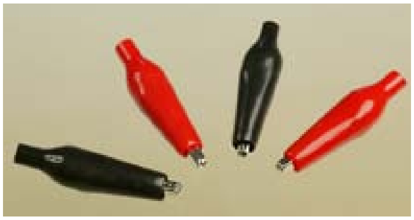

Figure 1-11. *Alligator clips inside vinyl sheaths, which reduce the chance of accidental short circuits.*

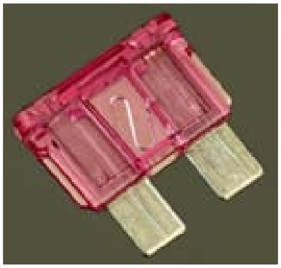

Figure 1-12. *A 3-amp fuse intended primarily for automotive use, shown here larger than actual size.*

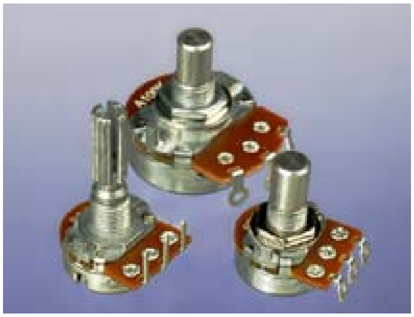

Figure 1-13. *Potentiometers come in many shapes and sizes, with different lengths of shafts intended for different types of knobs. For our purposes, any style will do, but the larger-sized ones are easier to play with.*

Battery holder for four AA cells, with wires attached (Figure 1-10). Quantity: 1. All Electronics catalog number BH-342 or RadioShack part 270-391 or similar.

Alligator clips

Vinyl-insulated. Quantity: at least 6. All Electronics catalog number ALG-28 or RadioShack part number 270-1545 or similar (Figure 1-11).

Components

You may not know what some of these items are, or what they do. Just look for the part numbers and descriptions, and match them with the photographs shown here. Very quickly, in the learning by discovery process, all will be revealed.

Fuses

Automotive-style, mini-blade type, 3 amps. Quantity: 3. RadioShack part number 270-1089, or Bussmann part ATM-3, available from automotive parts suppliers such as AutoZone (Figure 1-12).

Or similar. A blade-type fuse is easier to grip with alligator clips than a round cartridge fuse.

Potentiometers

Panel-mount, single-turn, 2K linear, 0.1 watt minimum. Quantity: 2. Alpha part RV170F-10-15R1-B23 or BI Technologies part P160KNPD-2QC25B2K, from Mouser.com or other component suppliers (Figure 1-13).

Or similar. The "watt" rating tells you how much power this component can handle. You don't need more than 0.5 watts.

Resistors

Assortment 1/4-watt minimum, various values but must include 470 ohms, 1K, and 2K or 2.2K. Quantity: at least 100. RadioShack part number 271-312.

Or search eBay for "resistor assorted."

Light-emitting diodes (LEDs)

Any size or color (Figures 1-14 and 1-15). Quantity: 10. RadioShack part number 276-1622 or All Spectrum Electronics part K/LED1 from Mouser.com.

Or similar. Just about any LEDs will do for these first experiments.

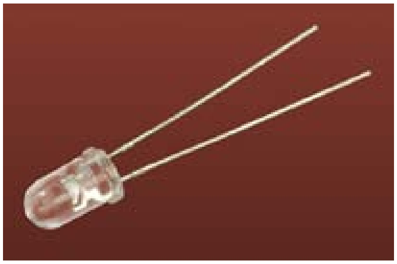

Figure 1-14. *Typical 5-mm diameter light-emitting diode (LED).*

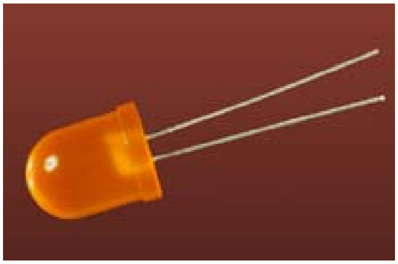

Figure 1-15. *Jumbo-sized LED (1 cm diameter) is not necessarily brighter or more expensive. For most of the experiments in this book, buy whatever LEDs you like the look of.*

Experiment 1: Taste the Power!

Can you taste electricity? Maybe not, but it feels as if you can.

You will need:

- 9-volt battery
- Snap connector for battery terminals
- Multimeter

No More Than 9 Volts

A 9-volt battery won't hurt you. But do not try this experiment with a higher-voltage battery or a larger battery that can deliver more current. Also, if you have metal braces on your teeth, be very careful not to touch them with the battery.

Procedure

Moisten your tongue and touch the tip of it to the metal terminals of a 9-volt battery. The sudden sharp tingle that you feel is caused by electricity flowing from one terminal of the battery (Figure 1-16), through the moisture on and in your tongue, to the other terminal. Because the skin of your tongue is very thin (it's actually a mucus membrane) and the nerves are close to the surface, you can feel the electricity very easily.

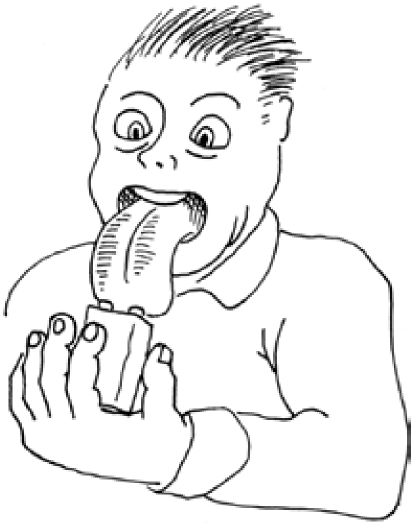

Figure 1-16. *Step 1 in the process of learning by discovery: the 9-volt tongue test.*

Now stick out your tongue, dry the tip of it very thoroughly with a tissue, and repeat the experiment without allowing your tongue to become moist again. You should feel less of a tingle.

What's happening here? We're going to need a meter to find out.

Tools

Setting up your meter

Check the instructions that came with the meter to find out whether you have to install a battery in it, or whether a battery is preinstalled.

Most meters have removable wires, known as *leads* (pronounced "leeds"). Most meters also have three sockets on the front, the leftmost one usually being reserved to measure high electrical currents (flows of electricity). We can ignore that one for now.

The leads will probably be black and red. The black wire plugs into a socket labeled "COM" or "Common." Plug the red one into the socket labeled "V" or "volts." See Figures 1-17 through 1-20.

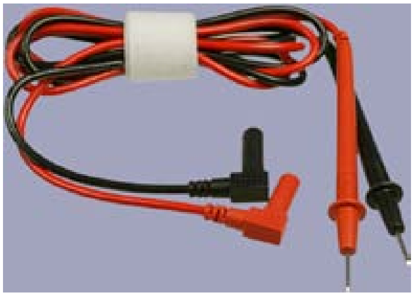

Figure 1-17. *The black lead plugs into the Common (COM) socket, and the red lead plugs into the red socket that's almost always on the righthand side of a multimeter.*

The other ends of the leads terminate in metal spikes known as *probes*, which you will be touching to components when you want to make electrical measurements. The probes detect electricity; they don't emit it in significant quantities. Therefore, they cannot hurt you unless you poke yourself with their sharp ends.

If your meter doesn't do autoranging, each position on the dial will have a number beside it. This number means "no higher than." For instance if you want to check a 6-volt battery, and one position on the voltage section of the dial is numbered 2 and the next position is numbered 20, position 2 means "no higher than 2 volts." You have to go to the next position, which means "no higher than 20 volts."

If you make a mistake and try to measure something inappropriate, the meter will show you an error message such as "E" or "L." Turn the dial and try again.

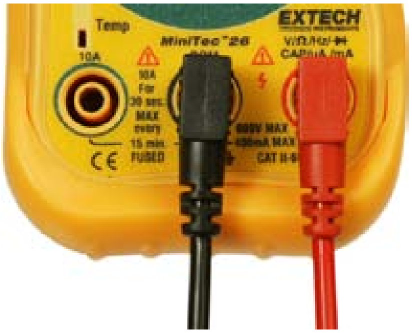

Figure 1-18

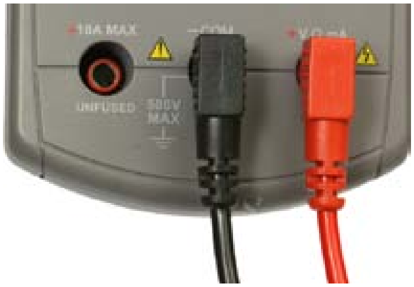

Figure 1-19

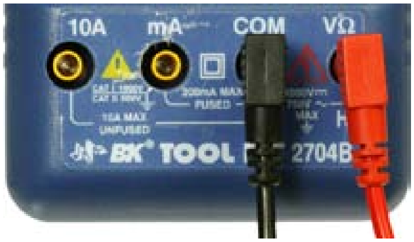

Figure 1-20. *To measure resistance and voltage, plug the black lead into the Common socket and the red lead into the Volts socket. Almost all meters have a separate socket where you must plug the red lead when you measure large currents in amps, but we'll be dealing with this later.*

FUNDAMENTALS

Ohms

We measure distance in miles or kilometers, weight in pounds or kilograms, temperature in Fahrenheit or Centigrade—and electrical resistance in ohms. The ohm is an international unit.

The Greek omega symbol (Ω) is used to indicate ohms, as shown in Figures 1-21 and 1-22. Letter K (or alternatively, KΩ) means a kilohm, which is 1,000 ohms. Letter M (or MΩ) means a megohm, which is 1,000,000 ohms.

A material that has very high resistance to electricity is known as an *insulator*. Most plastics, including the colored sheaths around wires, are insulators.

A material with very low resistance is a *conductor*. Metals such as copper, aluminum, silver, and gold are excellent conductors.

Number of ohms	Usually expressed as	Abbreviated as
1,000 ohms	1 kilohm	1KΩ or 1K
10,000 ohms	10 kilohms	10KΩ or 10K
100,000 ohms	100 kilohms	100KΩ or 100K
1,000,000 ohms	1 megohm	1MΩ or 1M
10,000,000 ohms	10 megohms	10MΩ or 10M

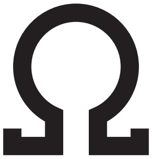

Figure 1-21. *The omega symbol is used internationally to indicate resistance on ohms.*

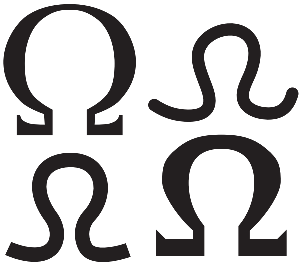

Figure 1-22. *You'll find it printed or written in a wide variety of styles.*

Procedure

We're going to use the meter to discover the electrical resistance of your tongue. First, set your meter to measure resistance. If it has autoranging, look to see whether it is displaying a K, meaning kilohms, or M, meaning megohms. If you have to set the range manually, begin with no less than 100,000 ohms (100K). See Figures 1-23 through 1-25.

Touch the probes to your tongue, about an inch apart. Note the reading, which should be around 50K. Now put aside the probes, stick out your tongue, and use a tissue to dry it very carefully and thoroughly. Without allowing your tongue to become moist again, repeat the test, and the reading should be higher. Finally, press the probes against the skin of your hand or arm: you may get no reading at all, until you moisten your skin.

> *When your skin is moist (for instance, if you perspire), its electrical resistance decreases. This principle is used in lie detectors, because someone who knowingly tells a lie, under conditions of stress, tends to perspire.*

A 9-volt battery contains chemicals that liberate electrons (particles of electricity), which want to flow from one terminal to the other as a result of a chemical reaction inside it. Think of the cells inside a battery as being like two water tanks—one of them full, the other empty. If they are connected with a pipe, water flows between them until their levels are equal. Figure 1-26 may help you visualize this. Similarly, when you open up an electrical pathway between the two sides of a battery, electrons flow between them, even if the pathway consists only of the moisture on your tongue.

Electrons flow more easily through some substances (such as a moist tongue) than others (such as a dry tongue).

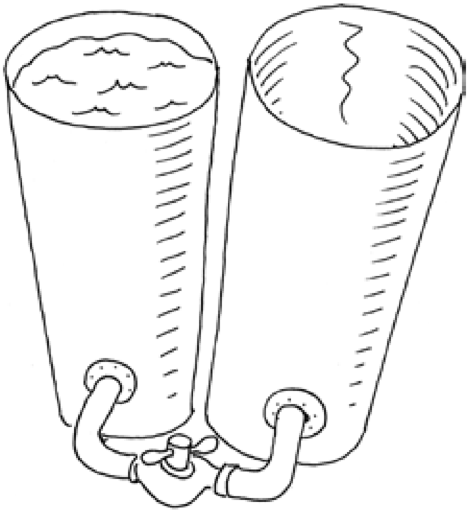

Figure 1-26. *Think of the cells in a battery as being like two cylinders: one full of water, the other empty. Open a connection between the cylinders, and the water will flow until the levels are equal on both sides. The less resistance in the connection, the faster the flow will be.*

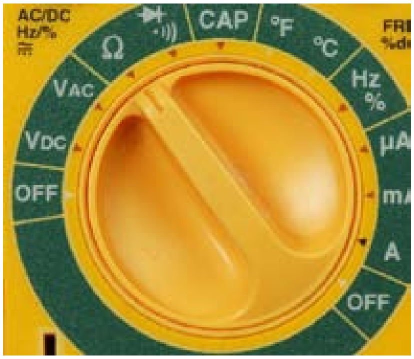

Figure 1-23

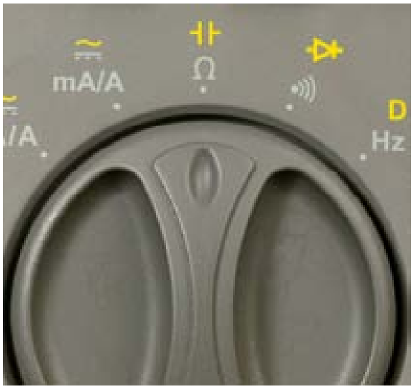

Figure 1-24

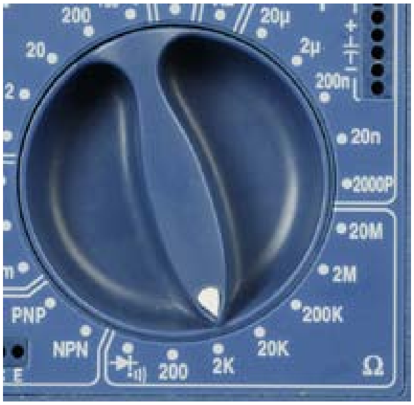

Figure 1-25. *To measure ohms, turn the dial to the ohm (omega) symbol. On an autoranging meter, you can then press the Range button repeatedly to display different ranges of resistance, or simply touch the probes to a resistance and wait for the meter to choose a range automatically. A manual meter requires you to select the range with the dial (you should set it to 100K or higher, to measure skin resistance). If you don't get a meaningful reading, try a different range.*

BACKGROUND

The man who discovered resistance

Georg Simon Ohm, pictured in Figure 1-27, was born in Bavaria in 1787 and worked in obscurity for much of his life, studying the nature of electricity using metal wire that he had to make for himself (you couldn't truck on down to Home Depot for a spool of hookup wire back in the early 1800s).

Despite his limited resources and inadequate mathematical abilities, Ohm was able to demonstrate in 1827 that the electrical resistance of a conductor such as copper varied in proportion with its area of cross-section, and the current flowing through it is proportional to the voltage applied to it, as long as temperature is held constant. Fourteen years later, the Royal Society in London finally recognized the significance of his contribution and awarded him the Copley Medal. Today, his discovery is known as Ohm's Law.

Figure 1-27. *Georg Simon Ohm, after being honored for his pioneering work, most of which he pursued in relative obscurity.*

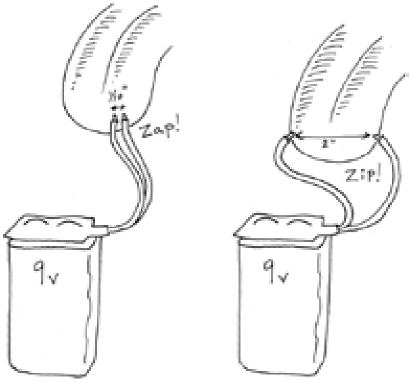

Figure 1-28. *Modifying the tongue test to show that a shorter distance, with lower resistance, allows greater flow of electricity, and a bigger zap.*

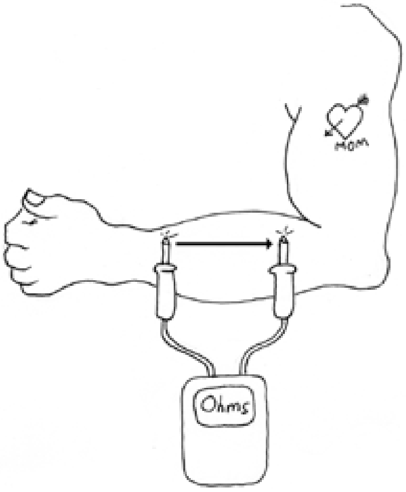

Figure 1-29. *Moisten your skin before trying to measure its resistance. You should find that the resistance goes up as you move the meter probes farther apart. The resistance is proportional to the distance.*

Further Investigation

Attach the snap-on terminal cap (shown earlier in Figure 1-8) to the 9-volt battery. Take the two wires that are attached to the cap and hold them so that the bare ends are just a few millimeters apart. Touch them to your tongue. Now separate the ends of the wires by a couple of inches, and touch them to your tongue again. (See Figure 1-28.) Notice any difference?

Use your meter to measure the electrical resistance of your tongue, this time varying the distance between the two probes. When electricity travels through a shorter distance, it encounters less total resistance. As a result, the current (the flow of electricity per second) increases. You can try a similar experiment on your arm, as shown in Figure 1-29.

Use your meter to test the electrical resistance of water. Dissolve some salt in the water, and test it again. Now try measuring the resistance of distilled water (in a clean glass).

The world around you is full of materials that conduct electricity with varying amounts of resistance.

Cleanup and Recycling

Your battery should not have been damaged or significantly discharged by this experiment. You'll be able to use it again.

Remember to switch off your meter before putting it away.

Experiment 2: Let's Abuse a Battery!

To get a better feeling for electrical power, you're going to do what most books tell you not to do. You're going to short out a battery. A short circuit is a direct connection between the two sides of a power source.

Short Circuits

Short circuits can be dangerous. Do not short out a power outlet in your home: there'll be a loud bang, a bright flash, and the wire or tool that you use will be partially melted, while flying particles of melted metal can burn you or blind you.

If you short out a car battery, the flow of current is so huge that the battery might even explode, drenching you in acid (Figure 1-30).

Lithium batteries are also dangerous. Never short-circuit a lithium battery: it can catch fire and burn you (Figure 1-31).

Use only an alkaline battery in this experiment, and only a single AA cell (Figure 1-32). You should also wear safety glasses in case you happen to have a defective battery.

You will need:

- 1.5-volt AA battery
- Single-battery carrier
- 3-amp fuse
- Safety glasses (regular eyeglasses or sunglasses will do)

Procedure

Use an alkaline battery. Do not use any kind of rechargeable battery.

Put the battery into a battery holder that's designed for a single battery and has two thin insulated wires emerging from it, as shown in Figure 1-32. Do not use any other kind of battery holder.

Use an alligator clip to connect the bare ends of the wires, as shown in Figure 1-32. There will be no spark, because you are using only 1.5 volts. Wait one minute, and you'll find that the wires are getting hot. Wait another minute, and the battery, too, will be hot.

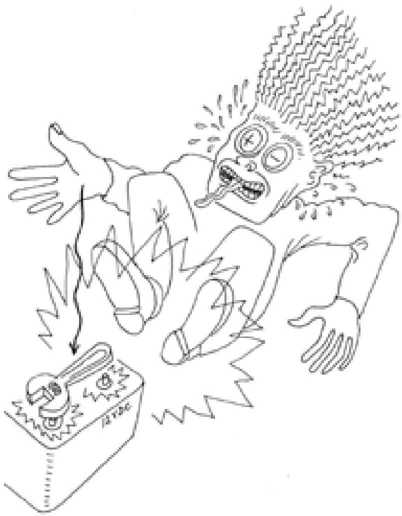

Figure 1-30. *Anyone who has dropped an adjustable wrench across the bare terminals of a car battery will tell you that short circuits can be dramatic at a "mere" 12 volts, if the battery is big enough.*

Figure 1-31. *The low internal resistance of lithium batteries (which are often used in laptop computers) allows high currents to flow, with unexpected results. Never fool around with lithium batteries!*

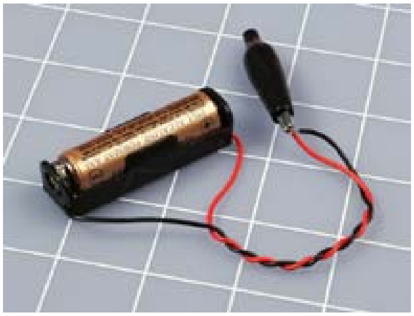

Figure 1-32. *Shorting out an alkaline battery can be safe if you follow the directions precisely. Even so, the battery is liable to become too hot to touch comfortably. Don't try this with any type of rechargeable battery.*

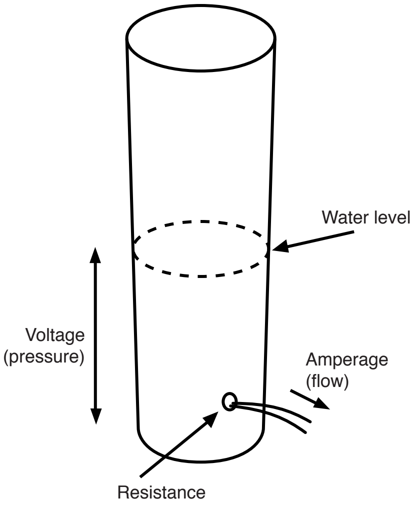

Figure 1-33. *Think of voltage as pressure, and amperes as flow.*

The heat is caused by electricity flowing through the wires and through the electrolyte (the conductive fluid) inside the battery. If you've ever used a hand pump to force air into a bicycle tire, you know that the pump gets warm. Electricity behaves in much the same way. You can imagine the electricity being composed of particles (electrons) that make the wire hot as they push through it. This isn't a perfect analogy, but it's close enough for our purposes.

Chemical reactions inside the battery create electrical pressure. The correct name for this pressure is *voltage*, which is measured in volts and is named after Alessandro Volta, an electrical pioneer.

Going back to the water analogy: the height of the water in a tank is proportionate to the pressure of the water, and comparable to voltage. Figure 1-33 may help you to visualize this.

But volts are only half of the story. When electrons flow through a wire, the flow is known as *amperage*, named after yet another electrical pioneer, André-Marie Ampère. The flow is also generally known as current. It's the current—the amperage—that generates the heat.

BACKGROUND

Why didn't your tongue get hot?

When you touched the 9-volt battery to your tongue, you felt a tingle, but no perceptible heat. When you shorted out a battery, you generated a noticeable amount of heat, even though you used a lower voltage. How can we explain this?

The electrical resistance of your tongue is very high, which reduces the flow of electrons. The resistance of a wire is very low, so if there's only a wire connecting the two terminals of the battery, more current will pass through it, creating more heat. If all other factors remain constant:

- Lower resistance allows more current to flow (Figure 1-34).
- The heat generated by electricity is proportional to the amount of electricity (the current) that flows.

Here are some other basic concepts:

- The flow of electricity per second is measured in amperes, or amps.
- The pressure of electricity causes the flow, measured in volts.
- The resistance to the flow is measured in ohms.
- A higher resistance restricts the current.
- A higher voltage overcomes resistance and increases the current.

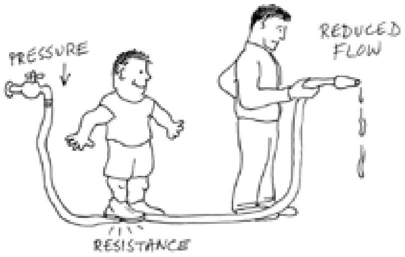

Figure 1-34. *Larger resistance results in smaller flow—but if you increase the pressure, it may overcome the resistance and increase the flow.*

If you're wondering exactly how much current flows between the terminals of a battery when you short it out, that's a difficult question to answer. If you try to use your multimeter to measure it, you're liable to blow the fuse inside the meter. Still, you can use your very own 3-amp fuse, which we can sacrifice because it didn't cost very much.

First inspect the fuse very carefully, using a magnifying glass if you have one. You should see a tiny S-shape in the transparent window at the center of the fuse. That S is a thin section of metal that melts easily.

Remove the battery that you short-circuited. It is no longer useful for anything, and should be recycled if possible. Put a fresh battery into the battery carrier, connect the fuse as shown in Figure 1-35, and take another look. You should see a break in the center of the S shape, where the metal melted almost instantly. Figure 1-36 shows the fuse before you connected it, and Figure 1-37 depicts a blown fuse. This is how a fuse works: it melts to protect the rest of the circuit. That tiny break inside the fuse stops any more current from flowing.

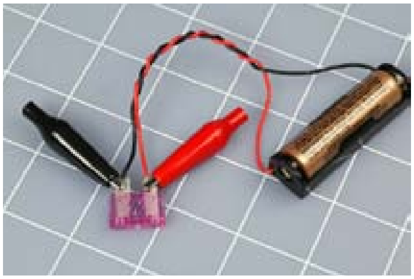

Figure 1-35. *When you attach both wires to the fuse, the little S-shaped element inside will melt almost instantly.*

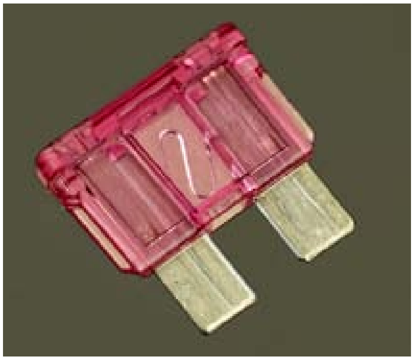

Figure 1-36. *A 3-amp fuse, before its element was melted by a single 1.5-volt battery.*

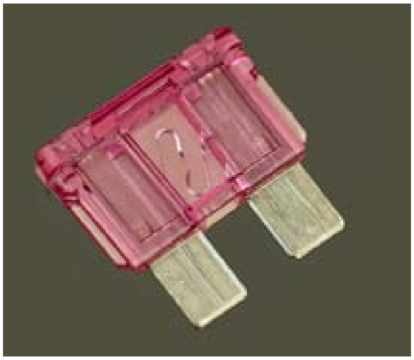

Figure 1-37. *The same fuse after being melted by electric current.*

FUNDAMENTALS

Volt basics

Electrical pressure is measured in volts. The volt is an international unit. A millivolt is 1/1,000 of a volt.

Number of volts	Usually expressed as	Abbreviated as
0.001 volts	1 millivolt	1 mV
0.01 volts	10 millivolts	10 mV
0.1 volts	100 millivolts	100 mV
1 volt	1,000 millivolts	1V

Ampere basics

We measure electrical flow in amperes, or amps. The ampere is an international unit, often referred to as an "amp." A milliamp is 1/1,000 of an ampere.

Number of amperes	Usually expressed as	Abbreviated as
0.001 amps	1 milliamp	1 mA
0.01 amps	10 milliamps	10 mA
0.1 amps	100 milliamps	100 mA
1 amp	1,000 milliamps	1A

BACKGROUND

Inventor of the battery

Alessandro Volta (Figure 1-38) was born in Italy in 1745, long before science was broken up into specialties. After studying chemistry (he discovered methane in 1776), he became a professor of physics and became interested in the so-called galvanic response, whereby a frog's leg will twitch in response to a jolt of static electricity.

Using a wine glass full of salt water, Volta demonstrated that the chemical reaction between two electrodes, one made of copper, the other of zinc, will generate a steady electric current. In 1800, he refined his apparatus by stacking plates of copper and zinc, separated by cardboard soaked in salt and water. This "voltaic pile" was the first electric battery.

Figure 1-38. *Alessandro Volta discovered that chemical reactions can create electricity.*

FUNDAMENTALS

Direct and alternating current

The flow of current that you get from a battery is known as *direct current*, or DC. Like the flow of water from a faucet, it is a steady stream, in one direction.

The flow of current that you get from the "hot" wire in a power outlet in your home is very different. It changes from positive to negative 50 times each second (in Great Britain and some other nations, 60 times per second). This is known as *alternating current*, or AC, which is more like the pulsatile flow you get from a power washer.

Alternating current is essential for some purposes, such as cranking up voltage so that electricity can be distributed over long distances. AC is also useful in motors and domestic appliances. The parts of an American power outlet are shown in Figure 1-39. A few other nations, such as Japan, also use American-style outlets.

For most of this book I'm going to be talking about DC, for two reasons: first, most simple electronic circuits are powered with DC, and second, the way it behaves is much easier to understand.

I won't bother to mention repeatedly that I'm dealing with DC. Just assume that everything is DC unless otherwise noted.

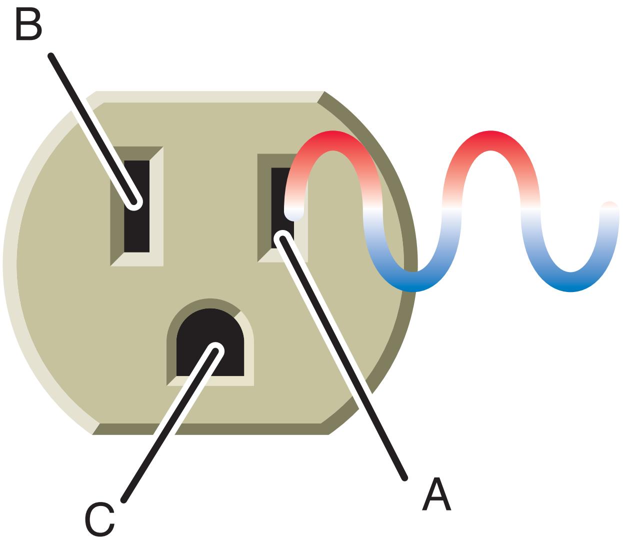

Figure 1-39. *This style of power outlet is found in North America, South America, Japan, and some other nations. European outlets look different, but the principle remains the same. Socket A is the "live" side of the outlet, supplying voltage that alternates between positive and negative, relative to socket B, which is called the "neutral" side. If an appliance develops a fault such as an internal loose wire, it should protect you by sinking the voltage through socket C, the ground.*

Cleanup and Recycling

The first AA battery that you shorted out is probably damaged beyond repair. You should dispose of it. Putting batteries in the trash is not a great idea, because they contain heavy metals that should be kept out of the ecosystem. Your state or town may include batteries in a local recycling scheme. (California requires that almost all batteries be recycled.) You'll have to check your local regulations for details.

The blown fuse is of no further use, and can be thrown away.

The second battery, which was protected by the fuse, should still be OK. The battery holder also can be reused later.

Experiment 3: Your First Circuit

Now it's time to make electricity do something that's at least slightly useful. For this purpose, you'll use components known as resistors, and a light-emitting diode, or LED.

You will need:

- 1.5-volt AA batteries. Quantity: 4.
- Four-battery holder. Quantity: 1.
- Resistors: 470Ω, 1K, and either 2K or 2.2K (the 2.2K value happens to be more common than 2K, but either will do in this experiment). Quantity: 1 of each resistor.
- An LED, any type. Quantity: 1.
- Alligator clips. Quantity: 3.

Setup

It's time to get acquainted with the most fundamental component we'll be using in electronic circuits: the humble resistor. As its name implies, it resists the flow of electricity. As you might expect, the value is measured in ohms.

If you bought a bargain-basement assortment package of resistors, you may find nothing that tells you their values. That's OK; we can find out easily enough. In fact, even if they are clearly labeled, I want you to check their values yourself. You can do it in two ways:

- Use your multimeter. This is excellent practice in learning to interpret the numbers that it displays.
- Learn the color codes that are printed on most resistors. See the following section, "Fundamentals: Decoding resistors," for instructions.

After you check them, it's a good idea to sort them into labeled compartments in a little plastic parts box. Personally, I like the boxes sold at the Michaels chain of crafts stores, but you can find them from many sources.

BACKGROUND

Father of electromagnetism

Born in 1775 in France, André-Marie Ampère (Figure 1-40) was a mathematical prodigy who became a science teacher, despite being largely self-educated in his father's library. His best-known work was to derive a theory of electromagnetism in 1820, describing the way that an electric current generates a magnetic field. He also built the first instrument to measure the flow of electricity (now known as a *galvanometer*), and discovered the element fluorine.

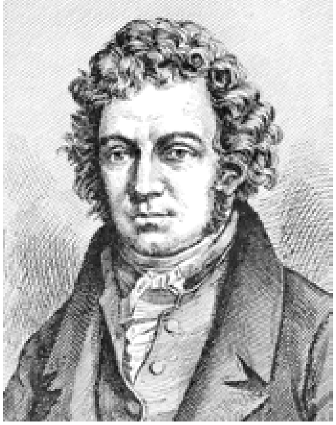

Figure 1-40. *Andre-Marie Ampere found that an electric current running through a wire creates a magnetic field around it. He used this principle to make the first reliable measurements of what came to be known as amperage.*

FUNDAMENTALS

Decoding resistors

Some resistors have their value clearly stated on them in microscopic print that you can read with a magnifying glass. Most, however, are color-coded with stripes. The code works like this: first, ignore the color of the body of the resistor. Second, look for a silver or gold stripe. If you find it, turn the resistor so that the stripe is on the righthand side. Silver means that the value of the resistor is accurate within 10%, while gold means that the value is accurate within 5%. If you don't find a silver or gold stripe, turn the resistor so that the stripes are clustered at the left end. You should now find yourself looking at three colored stripes on the left. Some resistors have more stripes, but we'll deal with those in a moment. See Figures 1-41 and 1-42.

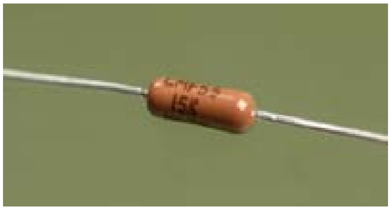

Figure 1-41. *Some modern resistors have their values printed on them, although you may need a magnifier to read them. This 15K resistor is less than half an inch long.*

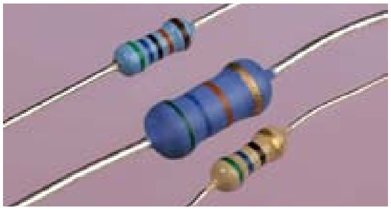

Figure 1-42. *From top to bottom, these resistor values are 56,000 ohms (56K), 5,600 ohms (5.6K), and 560 ohms. The size tells you how much power the resistor can handle; it has nothing to do with the resistance. The smaller components are rated at 1/4 watt; the larger one in the center can handle 1 watt of power.*

Starting from the left, the first and second stripes are coded according to this table:

Black	0
Brown	1
Red	2
Orange	3
Yellow	4
Green	5
Blue	6
Violet	7
Gray	8
White	9

The third stripe has a different meaning: It tells you how many zeros to add, like this:

Black	-	No zeros
Brown	0	1 zero
Red	00	2 zeros
Orange	000	3 zeros
Yellow	0000	4 zeros
Green	00000	5 zeros
Blue	000000	6 zeros
Violet	0000000	7 zeros
Gray	00000000	8 zeros
White	000000000	9 zeros

FUNDAMENTALS

Decoding resistors (continued)

Note that the color-coding is consistent, so that green, for instance, means either a value of 5 (for the first two stripes) or 5 zeros (for the third stripe). Also, the sequence of colors is the same as their sequence in a rainbow.

So, a resistor colored brown-red-green would have a value of 1-2 and five zeros, making 1,200,000 ohms, or 1.2MΩ. A resistor colored orange-orange-orange would have a value of 3-3 and three zeros, making 33,000 ohms, or 33KΩ. A resistor colored brown-black-red would have a value of 1-0 and two additional zeros, or 1KΩ. Figure 1-43 shows some other examples.

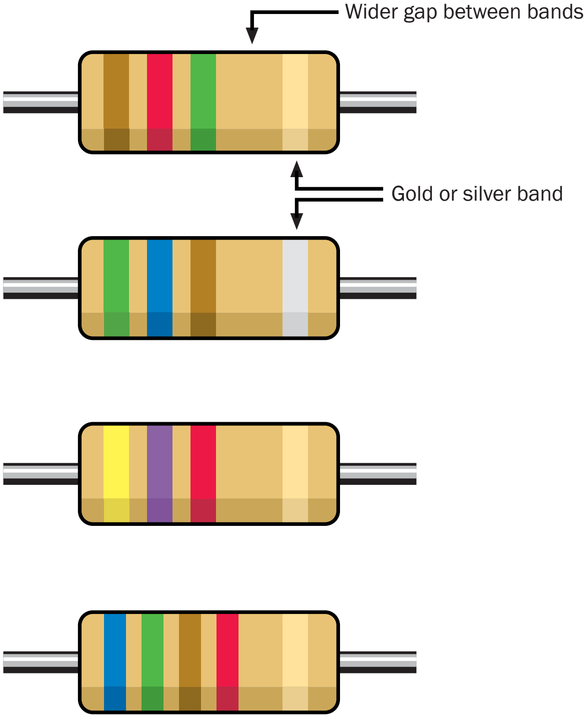

Figure 1-43. *To read the value of a resistor, first turn it so that the silver or gold stripe is on the right, or the other stripes are clustered on the left. From top to bottom: The first resistor has a value of 1-2 and five zeros, or 1,200,000, which is 1.2MΩ. The second is 5-6 and one zero, or 560Ω. The third is 4-7 and two zeros, or 4,700, which is 4.7KΩ. The last is 6-5-1 and two zeros, or 65,100Ω, which is 65.1KΩ.*

If you run across a resistor with four stripes instead of three, the first *three* stripes are digits and the *fourth* stripe is the number of zeros. The third numeric stripe allows the resistor to be calibrated to a finer tolerance.

Confusing? Absolutely. That's why it's easier to use your meter to check the values. Just be aware that the meter reading may be slightly different from the claimed value of the resistor. This can happen because your meter isn't absolutely accurate, or because the resistor is not absolutely accurate, or both. As long as you're within 5% of the claimed value, it doesn't matter for our purposes.

Lighting an LED

Now take a look at one of your LEDs. An old-fashioned lightbulb wastes a lot of power by converting it into heat. LEDs are much smarter: they convert almost all their power into light, and they last almost indefinitely—as long as you treat them right!

An LED is quite fussy about the amount of power it gets, and the way it gets it. Always follow these rules:

- The *longer* wire protruding from the LED must receive a *more positive* voltage than the shorter wire.
- The voltage difference between the long wire and the short wire must not exceed the limit stated by the manufacturer.
- The current passing through the LED must not exceed the limit stated by the manufacturer.

What happens if you break these rules? Well, we're going to find out!

Make sure you are using fresh batteries. You can check by setting your multimeter to measure volts DC, and touching the probes to the terminals of each battery. You should find that each of them generates a pressure of at least 1.5 volts. If they read slightly higher than this, it's normal. A battery starts out above its rated voltage, and delivers progressively less as you use it. Batteries also lose some voltage while they are sitting on the shelf doing nothing.
